Stanford Encyclopedia of Philosophy Abridged Table of Contents

Assigned Entries Only

Welcome to the Stanford Encyclopedia of Philosophy, which was designed from its inception (September 1995) as a *dynamic* reference work. In a dynamic reference work, each entry is maintained and kept up to date by an expert or group of experts in the field. These authors are given remote electronic access to copies of their entries on our server and they can update those copies any time the need arises. Moreover, all entries and updates are refereed by the members of a distinguished Editorial Board *before* they are made public. Whenever an author uploads a new entry or modifies an existing entry, the new material is stored off-line until it is approved by the Editorial Board member in charge of that entry. Consequently, our dynamic reference work is *responsive* to new research, for it can change at any time with the addition of new entries or the modification of existing entries. You can, however, cite fixed editions which are made on a quarterly basis and stored in our Archives. Thank you for your patience as our Encyclopedia develops. (Many of the assigned entries below have not yet been written.) See the Unabridged Table of Contents for the complete list of projected and assigned entries.

Stanford Encyclopedia of Philosophy Editorial Information

Basic Information

The *Stanford Encyclopedia of Philosophy* is a dynamic reference work and is a publishing project of the Metaphysics Research Lab at the Center for the Study of Language and Information (CSLI) at Stanford University. The concept of a dynamic reference work was implemented in the design of the Encyclopedia by Edward N. Zalta (Director of the Metaphysics Research Lab). The project began when John Perry was the Director of the Center for the Study of Language and Information. All correspondence should be directed to:

editors@plato.stanford.edu

Information about our dynamic reference work can be found in the following papers and abstracts:

- "The Stanford Encyclopedia of Philosophy: A Developed Dynamic Reference Work", by Colin Allen, Uri Nodelman, and Edward N. Zalta, forthcoming *Metaphilosophy* (285K PDF file); to be reprinted in *CyberPhilosophy: The Intersection of Philosophy and Computing*, James H. Moor and Terrell Ward Bynum, (eds.), Oxford: Blackwell, 2002
- "A Solution to the Problem of Updating Encyclopedias", by Eric Hammer and Edward N. Zalta *Computers and the Humanities*, **31**/1 (1997): 47-60 [Note: The ftp-based file upload system described in this paper has been superseded by a browser-based file upload system which uses special password-protected web interfaces for the authors and editors.]

Editorial Policies:

1. Editorial decisions concerning the *Encyclopedia*, including decisions concerning its content, format and distribution, are made by the Principal Editor in consultation with the Associate Editor, Assistant Editor, and the Board of Editors.
2. The members of the Board of Editors are selected in consultation with the Stanford Department of Philosophy, which serves as the *Encyclopedia*'s Advisory Board. The Advisory Board also advises the Principal Editor on the basic policies governing the operation of the *Encyclopedia*.
3. Contributions to the *Encyclopedia* are normally solicited by invitation from a member of the Board of Editors. However, *qualified* potential contributors may send a proposal to write on an *Encyclopedia topic*, and a *curriculum vitae* or other description of their qualifications, to an appropriate member of the Editorial Board.
   - By *qualified*, we mean those persons with accredited Ph.D.s in Philosophy (or a related discipline) who have published *refereed works* on the topic of the proposed entry. By *refereed works* we mean either articles in respected, refereed journals or books which have been published by respected publishing houses and which have undergone the usual peer review process prior to publication. (Notes in newsletters, proceedings, unpublished dissertations, etc., do not count as much.) However, if a member of our Board of Editors is familiar with the work of the potential contributor, the latter may be certified as qualified.
   - By *Encyclopedia topic*, we mean a topic that is suitable for a reference work in philosophy and is (a) either listed in our Unabridged Table of Contents or (b) falls within the area of expertise of one of the members of our Editorial Board. Since the *Encyclopedia* currently does not yet have subject editors for every specialized area of philosophy, some topics suitable for a reference work in philosophy might fail condition (b) -- we reserve the right to determine whether such entry proposals (in specialized areas for which the Encyclopedia lacks subject editors) should be pursued at this time.

   The Board of Editors reserves the right to compare the qualifications of any person submitting an unsolicited request with those of other potential authors who might naturally come to mind for the entry in question.
4. Readers of the *Encyclopedia* are encouraged to contact authors directly with comments, corrections, and other suggestions for improvements.
5. It remains the responsibility of authors to maintain their entries and to keep them current. Authors are expected: (1) to update their entries regularly, especially in response to important new research on the topic of the entry, and (2) to revise their entries *in a timely way* in light of any valid criticism they receive, whether it comes from the subject editors on our Editorial Board, other members of the profession, or interested readers. In connection with (1), authors should

update the Bibliography and Other Internet Resources sections of their entries regularly, to keep pace with significant new publications, both in print and on the web. In connection with (2), the validity of criticism shall be determined by the Principal Editor, typically in consultation with the relevant members of the Editorial Board. The length of time required for a "timely" revision will be negotiable and will both respect the author's current commitments and reflect the seriousness of the criticism. However, entries which require revision but which are not revised within the negotiated timetable may be retired from the active portion of the *Encyclopedia* and left in the *Encyclopedia* Archives until such time as the entry is revised so as to engage the valid criticisms in question.
6. The views expressed by the authors in their entries are their own and do not necessarily reflect those of Stanford University, the Stanford University Philosophy Department, the *Encyclopedia*'s Editor or of anyone else associated with the *Encyclopedia*.

Copyright Information

Copyright Notice. Authors contributing an entry or entries to the *Stanford Encyclopedia of Philosophy* retain copyright to their entry or entries but grant to the Metaphysics Research Lab at Stanford University an exclusive license to publish their entry or entries on the Internet and the World Wide Web, including any future technologies or media that develop to supplement or replace the Internet or World Wide Web. All rights not expressly granted to the Metaphysics Research Lab at Stanford University, including the right to publish an entry or entries in other print media, are retained by the authors. Copyright of the *Stanford Encyclopedia of Philosophy* itself is held by the Metaphysics Research Lab at Stanford University. All rights are reserved. No part of the *Encyclopedia* (excluding individual contributions and works derived solely from those contributions, for which rights are reserved by the individual authors) may be reprinted, reproduced, stored, or utilized in any form, by any electronic, mechanical, or other means, now known or hereafter invented, including printing, photocopying, saving (on disk), broadcasting or recording, or in any information storage or retrieval system, other than for purposes of fair use, without written permission from the copyright holder. (All communications should be directed to the Principal Editor.)

Licensing Agreement. By contributing to the *Stanford Encyclopedia of Philosophy* authors grant to the Metaphysics Research Lab at Stanford University a perpetual, exclusive, worldwide right to copy, distribute, transmit and publish their contribution on the Internet and World Wide Web. The authors also grant to the Metaphysics Research Lab at Stanford University a perpetual, non-exclusive, worldwide right to copy, distribute, transmit and publish any and all derivative works prepared or modified by the Editors from the original contribution, in whole or in part, by any variety of methods on all types of publication and broadcast media other than the Internet, now known or hereafter invented. Authors also grant to the Metaphysics Research Lab at Stanford University a perpetual, non-exclusive, worldwide right to translate their contribution, as well as any modified or derivative works, into any and all languages for the same purposes of copying, distributing, transmitting and

publishing their work.

Statement of Liability. By contributing to the *Stanford Encyclopedia of Philosophy* authors grant, to the Principal Editor, the Associate Editor, the Assistant Editor, members of the Advisory and Editorial Boards, the Metaphysics Research Lab, CSLI, and Stanford University, immunity from all liability arising from their work. All authors are responsible for securing permission to use any copyrighted material, including graphics, quotations, and photographs, within their contributions. The Principal Editor, Associate Editor, Assistant Editor, members of the Advisory and Editorial Boards, CSLI, and Stanford University therefore disclaim any and all responsibility for copyright violations and any other form of liability arising from the content of the *Encyclopedia* or from any material linked to the *Encyclopedia*. Alleged copyright violations should be brought to the attention of the author and the Principal Editor, so that such issues may be dealt with promptly.

Acknowledgements*:*

The Stanford Encyclopedia of Philosophy project is indebted to various people, both at Stanford and elsewhere, all of whom deserve acknowledgement. Although the Associate Editor and the Assistant Editor have been the main Perl programmers on this project since 1998, Eric Hammer, programmed on the project from 1995 to 1997. During the 2000-2001 and 2001-2002 academic years, David James Anderson wrote important Perl programs and has made other contributions to the project. We'd also like to thank David Barker-Plummer, Mark Greaves, Emma Pease, and Susanne Riehemann for their many helpful suggestions concerning the *Encyclopedia* project and the construction of this Web site.

The Principal Editor would also like to acknowledge the contributions of: Javier Ergueta, for his efforts and work in developing a business plan for the Stanford Encyclopedia of Philosophy during the first six months of 2002, and Nathan Tawil, who helped design the Encyclopedia entry format when the project started in 1995. Finally, the South Korean company C.O.Tech, Inc., deserves acknowledgement for their expert advice concerning XML and for working on a Java-based, graphical XML/XHTML-editing program for our consideration and possible use by the authors of the Encyclopedia.

1 Introduction

A fundamental problem faced by the general public and the members of an academic discipline in the information age is how to find the most authoritative, comprehensive, and up-to-date information about an important topic. The present information explosion is the source of this problem—more ideas than ever before are being published in print, on CD-ROM, and in a variety of forms on the Internet. One can nowadays use library search engines and web-indexing engines to generate lists of publications and websites about a topic and then access them immediately if they are

online. But even limited area search engines can produce thousands of matches to keywords and even with new interface tools to narrow the search, one is typically confronted with a list that is not informed by human judgment. If one wants an introduction to a topic that is organized by an expert, if one wants a summary of the current state of research, or if one wants a bibliography of print and online works that has been filtered on the basis of informed human judgment, there are few places to turn. One might try a standard reference work, but the main problem with reference works is that they quickly go out of date (even before they are published) and don't reflect the latest advances in research. So the following questions arise: How can an academic discipline maintain a reference work which introduces the significant topics in the field (for those who wish to learn the basics), but which tracks, evaluates, and changes in response to new publications and new research being presented in a variety of media (for those with advanced knowledge on a given topic)? How can this be done so that access to the reference work is low-cost, if not free?

Members of our project started thinking about these questions in 1995, and in order to answer them, we developed and implemented the concept of a 'dynamic reference work' (DRW). A DRW is much more than a web-based encyclopedia. The most important features of a DRW are that: (1) it provides the authors (who may be scattered in universities all over the world) with electronic access to their entries, so that they can update those entries at any time to reflect advances in research, (2) it provides the subject editors (wherever they are located) with administrative access to those entries and updates, by which they can referee them prior to publication (and by which they can add new topics, commission new authors, etc.), and (3) it provides automated tools by which a principal editor can oversee administrative control of (1) and (2) with only a small staff. Thus, on our conception, a DRW includes a highly customized work-flow system by which the members of an entire discipline are empowered to collaboratively write *and maintain* a refereed resource. Such a resource would not only introduce traditional topics in the discipline, but would also track the (new) ideas that are constantly being published on those topics in a variety of media. With this concept of a DRW, all sorts of new and interesting questions arise concerning how to best design, program, and administer such a resource and work-flow system.

No electronic journal or preprint exchange in the sciences or human-

ities approaches this concept in scope. Electronic journals: (1) typically do not update the articles they publish, (2) do not aim to publish articles on a comprehensive set of topics, but rather, for the most part, publish articles that are arbitrarily submitted by the members of the profession, (3) typically serve a narrow audience of specialists, and (4) do not have to deal with the *asynchronous* activity of updating, refereeing, and tracking separate deadlines for entries, since they are published on a *synchronized* schedule. Preprint exchanges not only exhibit features (1), (2), and (3), but also do not referee their publications and so need not incorporate a work-flow system that handles the asynchronous referee process that occurs between upload and publication in a DRW. None of this is to say that electronic journals and preprint exchanges have a faulty design, but rather that a DRW is a distinctive new kind of publication that represents a new digital library concept.

Although commercial publishers have built web-based reference works and claim that they are dynamic, they lack some of the principal design features of a DRW, namely, (1) that authors should have electronic access to copies of their entries and be able to modify them, and (2) that subject editors and the principal editor should have electronic access to the encyclopedia databases and unrefereed entries, so that they can directly carry on the task of adding and commissioning new entries, refereeing entries and updates, etc. These commercial publishers typically don't give academics accounts on their computers, or access to their databases. Instead, the authors and editors must provide/referee content by first interacting with the staff of the publishing house (managing editors, copy editors, computer web specialists, computer markup specialists and others) before changes to the encyclopedia can be made public. On our model, however, the *publishing house* becomes inessential to the process of maintaining a DRW. Academics have direct electronic access to the entries, and can engage and manage the process of writing, refereeing, and updating entries without intermediaries.

Our implementation of a DRW is embodied by the Stanford Encyclopedia of Philosophy (SEP) <http://plato.stanford.edu/>. In the remainder of this paper, we document this particular DRW and then discuss some of the outstanding questions and problems it faces.

2 The Implementation of a Dynamic Reference Work

The SEP first came online in September 1995 with 2 entries! Since then, we have designed a workflow system which attempts to maximize efficiency among those involved in its production. The most important parts of this system are the password-protected web interfaces to the central server, which can be accessed by any author, subject editor, or the principal editors from any where in the world there is a computer with an internet connection.[1]

The web interface for authors allows them to download our HTML templates, to upload their new entries into a private area of our web server, and to remotely edit copies of their entries stored in this private area. So if an author is lecturing outside her university and encounters a reader of her entry who points out an error or omission, she can sit down at the next net-connected computer (possibly at an Internet cafe), contact the Stanford server using the machine's web browser and, after supplying her ID and password, remotely edit the content of her piece and submit it for editorial review. The web interface for subject editors allows them to enter new topics, commission authors for those topics, referee and comment on entries and updates submitted for review, and communicate their decisions to the editor. So, for example, if a subject editor is visiting another university and learns by email that an entry has

[1]These web interfaces, and the file download and file upload capacities which they enable, are the principal enhancements we've made to the SEP since the publication of the paper 'A Solution to the Problem of Updating Encyclopedias', by E. Hammer and E. Zalta, in *Computers and the Humanities*, **31**/1 (1997): 47–60. When that paper was published, the SEP still used an ftp-based file-upload system. We gave authors system accounts on our Unix server, linked their home directories into webspace, and allowed authors to transfer their files by ftp to our server. However, subsequent to the 1997 paper, when browser-based file upload had become a widely adopted and supported standard, we switched to the new technology. Authors and subject editors no longer needed system accounts on our Unix server, and indeed we determined that maintaining Unix accounts for all participants would introduce problems of scale when dealing with hundreds of accounts. Furthermore, we improved security on our machine by deleting those accounts. Instead, authors were given passwords for the browser-based file-uploads. Moreover, subsequent to the 1997 paper, we distinguished a private 'upload-space' (which includes 'revision space') from our public 'web-space'. The former contains private copies of the entries accessible only to authenticated users so that newly uploaded entries, and newly revised entries, do not become publicly viewable until after they have passed through the referee process.

been revised and submitted for review (see the discussion of our tracking and reminder system below), she can use a web browser to log onto the subject editors web interface, display the original and revised versions of the entry side-by-side *with the differences highlighted*, easily determine where the changes are located, referee them, and then accept or reject revised version.

The principal editor also has a special, secure web interface, by which this collaborative process is administered. The principal editor can easily add people to the project, add entries to the database, assign editorial control for entries to the subject editors, issue invitations, track deadlines (for new entries and for updates), and publish entries and updates when they are ready. Many of these things can be done with just the press of a few electronic buttons. For example, when a subject editor submits (through her web interface) a suggestion to commission an author on a particular topic, the suggestion gets entered into a database, and the principal editor is notified and prompted to log onto his web interface. He simply hits the New Invitation button, selects the entry in question, and is then prompted to invite the person listed in the database for that entry by hitting the Invite button.

Finally, we should mention that we have designed and implemented a web interface for *prospective* authors. When a prospective author receives an invitation, they are directed to log on to a special web interface to obtain information about the project, to set up an account with us if they plan to accept, and to set a deadline of up to a year for completing the entry (or else write to us with a counterproposal).

These 'front-end' web interfaces supply data to the 'back-end' processing programs and databases in our system. In particular, actions taken, and information entered, by authors, editors, and prospects are communicated to our tracking and logging system. This system can identify the state of any given entry, recognize who now owes work on an entry and which deadlines have or haven't been met, and pass this information to our automated email reminder system, which has recently been developed, initialized, and put into continuous operation. When an entry changes state and another person must now act to continue the publication process, the reminder system will prompt this person about what needs to be done and by when. It will continue to send reminders (on a fixed, inoffensive schedule) until the work is done (or notify the principal editor that that all reminders have been ignored and that human

intervention needs to take place). Finally, when any entry or substantive revision is published, the entry is scheduled for revision within 3-5 years (depending on how swiftly the field moves). Actually, some authors update once a year, but all authors are notified by our reminder system well in advance of any scheduled revision.

The use of these web and computer technologies offers considerable savings over more traditional publishing methods, and has enabled us to develop the Encyclopedia with a small staff and budget. The importance of this project for our profession cannot be overstated. As new ideas in logic, ethics, political philosophy, philosophy of science, philosophy of cognitive science, etc., are published in books and journals of philosophy, both in print and on the web, the SEP provides a rational and efficient system by which the new information is assimilated, digested, and disseminated in entries which are *responsive* to new research.

Here is a basic quantitative analysis of the effectiveness of our design which is justified by the above. Consider first the fact that there was a 30-year gap between philosophy encyclopedias (the Macmillan Encyclopedia was published in 1967, the Routledge Encyclopedia in 1998). So there was no up-to-date encyclopedia for at least 25 years (9125 days). By contrast, a typical Encyclopedia author is regularly visiting the library to read journals or receiving new journal issues at her office. As soon as she realizes that a recently published article advances the topic of her Encyclopedia entry (and, in principle, this could be the day that an article is published, and in some cases, she might even have advance knowledge of the publication if the author has sent her a preprint), she can use her computer to call up the Encyclopedia server and modify her entry accordingly (maybe by adding a paragraph and a Bibliographic item). The next day, assuming that the change is a substantive one, the relevant subject editor(s) will be notified that the revision must be refereed. Suppose it takes a week to referee the minor changes to her entry. Then we have reduced the length of time required for the update process from about 9,000 days to about 9 days, or by 3 orders of magnitude. Even if it were to take up to a year for a new idea (in a book, say) to become reflected in the Encyclopedia after the new idea is published, that would still constitute a 25-fold decrease in the length of time it takes for a philosophy reference work to reflect the advance.

We should mention two other features of the SEP which should be part of any DRW. The first is the fact that authors are encouraged to

write nested, as opposed to linear, documents. That is, we encourage our authors to put highly technical, scholarly, or highly detailed information into supplementary documents and to link these into the main part of the entry. These supplementary documents can have supplements as well, and so forth, and so the reader can then choose the level of detail they wish to explore. Such nested entries become useful to a wider range of readers — intelligent undergraduates should be able to get through the main entry by skipping the links to the supplements, while graduate students and colleagues may skip the basics and follow the links to the supplementary documents, to find the cutting edge material.

The second noteworthy feature concerns archiving. For purposes of citation, a DRW is a moving target, since the entries are always being corrected, updated, improved, etc. It is difficult to cite such a moving target. For example, a reader might quote a passage from a DRW entry in a research article, and after publishing the research article, discover that the author of the DRW entry has altered the passage in question. To solve this problem, we make quarterly archives of the SEP. On the equinoxes and solstices, we make an electronic copy or 'snapshot' of the entire encyclopedia as it exists on that day and link that complete copy into our special Archives page. We explain to users that the proper way to cite an SEP entry is to cite the most recent archived version. These archived versions will not be updated or changed in any way, and so scholars can rest assured that the passages they quote will be available for scholarly purposes. Note that every entry in the SEP contains a section called Other Internet Resources which contains links to offsite web-based material and these links may eventually break in the archived entries (especially if the links do not point to similarly archived material). That is a danger of the web. But we do attempt to minimize the problem, however. We have designed and programmed a 'link-rot' detection system which automatically notifies the authors anytime links break in the dynamic versions of their SEP entries. The authors are asked to revise or delete the link.

3 Statistics about the SEP as a Dynamic Reference Work

As of September 21, 2001, the SEP had 213 entries online. We had 69 subject editors overseeing 513 authors currently working on a total of 600

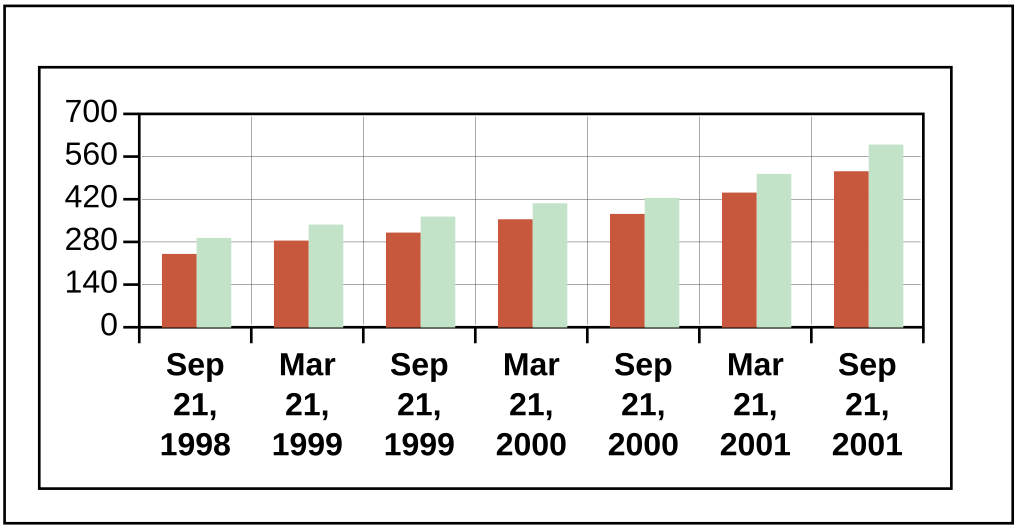

Figure 1: Number of Authors/Commissioned Entries

commissioned entries.

Over 10% of our entries make use of some hierarchical document structure (i.e., they involve more documents than simply a main text and a footnotes page) and just under half of our entries have been updated since they were first published.

The rate at which we commission entries increased by a factor of 3, from about 5 per month in 1999 and 2000 to about 15 per month in 2001. See Figure 1. During the same period, our publishing rate increased by a factor of 6, from about 1.5 entries per month in 1999 to 9 entries per month in 2001. See Figure 2. The average length of our entries also increased from approximately 6800 words per entry in September 1998 to 8900 words per entry currently.[2] We estimate that, in print, the current version of the SEP would fill over 3000 pages.[3]

Between September 1997 and September 2001, the content of the SEP grew from about 3 megabytes to about 26 megabytes. See Figure 3. During that same period our average accesses per month increased by an order of magnitude, from about 5000 to 57000. See Figure 4.

[2]These word counts are slightly inflated due to the presence of HTML tags in the text. We estimate that the tags add about 300 to 500 words per entry.

[3]This estimate is based on an assumption of 600 words per page.

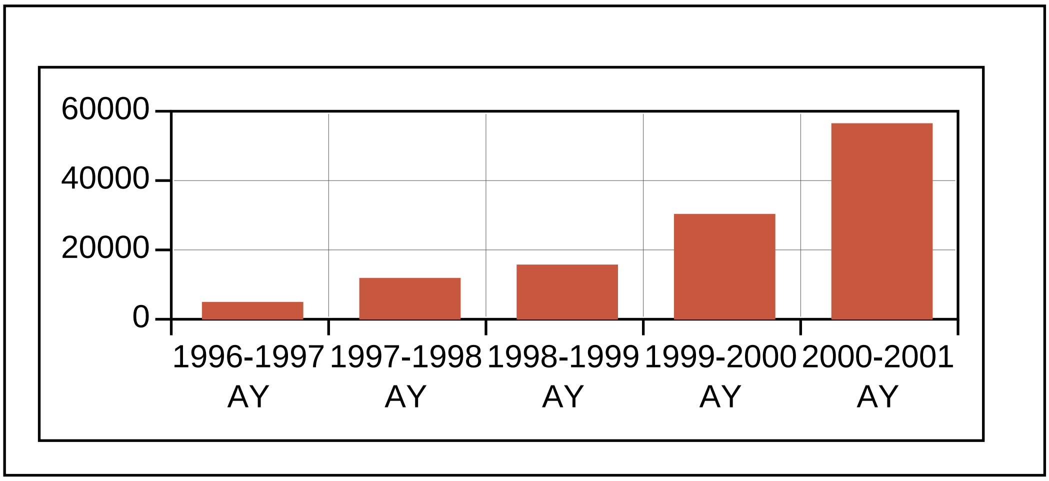

Figure 4: Weekly Average Number of Users (Excluding Mirror Sites)

4 Why the SEP (and other DRWs) Should Be Free

After 6 years of operation and numerous discussions with authors and subject editors involved with our project, with faculty members and colleagues around the world, with publishers, and with university librarians, we have come to the conclusion that if the means are possible, the SEP should try to remain a free resource. One may think of this as an idealistic goal, but there are several problems associated with a subscription-based, access-restricted models for funding the SEP. We discuss some of these problems in what follows.

The first problem arises from the fact that academics who author entries in scholarly reference works traditionally receive a fee for their efforts. They are, after all, providing a service to the publisher. However, authors of SEP entries are volunteering their time. There are various reasons why they do this. One might be the fact that they will reach a large number of readers. (As long as the SEP remains free or low-cost, it will have a large readership.) Another might be the intellectual obligation academics might feel they have to contribute to the profession and world at large by playing a role in maintaining an up-to-date resource

in philosophy. Another might be the prestige they might acquire should they become known widely as an expert on a certain topic, or by becoming associated with a Stanford University project. And, of course, authors may be motivated by the fact that they can list these entries as invited publications on their curricula vitae, which play an important role in promotion, hiring, and tenure.

This volunteer arrangement, however, might become compromised if the SEP were required to charge subscriptions in the attempt to make a profit. Even if the SEP charged subscriptions at a rate that simply recovers costs, authors might suggest both that we should recognize their efforts as part of that cost and that we should therefore increase prices a little so as to collect enough revenue to distribute royalties to the authors. The situation is complicated, moreover, by the fact that authors might *additionally* argue that maintaining an entry is also a service. In any year they update their entry, they might be owed remuneration. As we scale up to 1000+ authors, this problem becomes even more acute. And a final wrinkle is the fact that our authors currently provide us with entries formatted in HTML and nearly 'web-ready'. If we charged a subscription, if only to recover costs, authors might claim that we are *offloading our typesetting costs* onto them. It would be best to sidestep all of these questions by finding a model on which the SEP could remain a free resource and our authors never feel that they are being exploited.

As second, somewhat similar, problem concerns our subject editors. These subject editors are constantly suggesting new entries, commissioning entries, and refereeing entries and updates. If we required subscriptions for access to the SEP, if only to recover costs, the subject editors might argue that their services should be recognized as part of those costs, and that we should increase our subscription rates to pay them accordingly. This problem is magnified by the fact that the work involved in maintaining a dynamic reference work continues from year to year, with no fixed endpoint, and it is complicated by the fact that some subject editors have higher workloads than others.

A third problem concerns the difficulty of finding a subscription model that everyone can live with. University libraries and other institutions are reluctant to pay for something the rest of the world can get for free. Consequently, it would be difficult to implement a model in which these institutions would pay a subscription fee while everyone else would be allowed free access. So a subscription model might eventually force us

to require *everyone* to subscribe (albeit, at appropriately proportional rates).

A fourth problem is the fact that many deserving groups of people would be disenfranchised by a subscription model. Small colleges, public libraries, and K-12 school libraries usually can not afford even a modest subscription fee. Moreover, people who are accessing the web from home over an ISP seem reluctant to pay for content, much less for a subscription to a *philosophy* encyclopedia. And last, but not least, our users in the developing parts of the world would become disenfranchised; this includes university students and colleagues in developing countries, as well as lay persons in those countries. Since the SEP has been accessed by users in over 150 countries around the world, academics associated with the project as authors would lose a significant base of readers.

A fifth problem concerns search engines. When people search Google, Yahoo, etc., for philosophical topics, our pages figure prominently in the results. That is because our pages are free to everyone, and web-indexing spiders can access and index our pages. But on a subscription model, our server would restrict access to those who pay. This would make it nearly impossible for search engines to index our site, and consequently people wouldn't find the SEP pages when they conduct web searches. Even if some arrangement could be made to allow indexing spiders to index our site, access restrictions would make the links returned by a search engine useless to the majority of web users, and make it difficult and pointless for non-paying users and institutions to create links to our site on their own pages. But without those thousands of links to the entries on our site, the prominence of our pages in the results of certain web search engines (e.g., Google) would greatly diminish, since those search engines often prioritize the websites which are returned as matches to keyword searches by the number of cross-referencing links to those websites that exist on the web.

A sixth problem concerns our mirror sites. Currently, the SEP has mirror sites (U. of Sydney, U. of Amsterdam, and, soon, U. of Leeds) which perform the following functions. (1) They guarantee our users access to the Encyclopedia pages when the Stanford server temporarily goes down. (If anything happens to our server, our readers use a mirror site until we fix the problem and reboot.) (2) These mirror sites give our users in other parts of the world faster access to our pages. (3) The mirror sites provide very important layers of digital preservation for the SEP pages by keeping complete copies of our data. These institutions

completely underwrite the costs of the mirror sites and provide this service for free. But this arrangement would come to an end if we started charging a subscription for our site. On a subscription model, either we would have to pay the mirror sites for their costs in manpower, equipment, and overhead (assuming that some monetary arrangement could be made), or we would have to face the much more expensive proposition of running 'mission critical' servers that provide fast, world-wide access 24 hours of every day. (If institutions have to pay for the SEP, they would expect a level of service at least comparable that which they now enjoy.)

A seventh problem is the fact that if the SEP were forced to rely on cost-recovery to survive, the decisions which are now made *in-part* on the basis of the interests of the profession may have to be made instead on the basis of cost recovery *alone*. This might have a negative impact on the quality of the Encyclopedia, such as placing strict word limitations on the length of entries and bibliographies (to save disk space or stay within bandwidth limitations), banner advertising, links to online booksellers, etc. The latter, for example, would compromise the integrity of the Encyclopedia, since a user might wonder whether the link to an online bookseller is present because of the merits of the book or because the online bookseller was kicking-back some of the profits to the publisher.

In addition to the above seven problems that would arise if the SEP adopted a access-restricted, subscription-based cost-recovery model, we believe that there is a positive reason for remaining free, namely, that it would be an outstanding legacy for the SEP and profession as a whole if it could provide both academics and non-academics around the world with a free resource by which they could satisfy their intellectual curiosity from an authoritative source on philosophical questions of all kinds and, in particular, those concerning the human condition.

5 Costs of the SEP

Of course, it does cost money to produce the SEP and if it is to remain free, those costs will somehow have to be underwritten. Currently, the SEP costs are underwritten by a grant from the NSF, which funds the SEP from October 2000 to September 2003.[4]

[4]The NSF grant (#IIS-9981549) was made possible by a significant financial contribution from the NEH. The NEH previously funded the Encyclopedia project from September 1998 to August 2000 (#PA-23167-98). From September 1995 to August

The NSF grant pays for a Principal Editor (working 50% time), a Consultant Perl Programmer (working 33% time), an Associate Programmer (working 20% time), an Assistant Programmer (working 10% time) and an Administrative Assistant (working 10% time).[5] Clearly, this adds up to a tiny staff, since the percentages total to one person at 100% employment and one at 23% employment. We believe our accomplishments are significant when viewed in light of our tiny staff, though it should be mentioned that these accomplishments were made possible by the fact that our personnel regularly put in longer hours than official records indicate. We are currently seeking grant money to hire a business consultant to determine exactly what costs are required to run/staff the SEP and what funding models are available to ensure that the SEP's long-term survival.

We believe that the SEP could evolve into an even greater publication (i.e., with even higher quality entries, with fewer typographical and other errors, etc.) if it had more adequate staffing. It does not strike us as unreasonable to think that the SEP should, for the long term, require a Principal Editor at 50% time, an administrative assistant at 50% time, a programmer at 50% time, and an HTML (XML) copy-editor at 50% time. With an administrative assistant and HTML copy-editor working at these levels, the Principal Editor would be relieved of certain routine tasks and could concentrate more on content issues, on supporting subject editors for those subjects of the SEP which still aren't very far along, etc. Similarly, with a programmer working half-time, we could re-engineer many of the compromises we made in designing and programming our workflow system, we could adapt the SEP to new technologies that improve web-based publication, etc. Although our estimate of these long-term staffing requirements for the SEP will need to be subjected to a strict business analysis, it should give the reader some idea of the money for salary income that the SEP will need. Once money for overhead costs (including hardware and software) are included in the equation, it should be clear that the SEP will have to find sources of income if it hopes to remain a free publication after the NSF grant expires.

1998, the SEP was funded by seed money from the Center for the Study of Language and Information (Stanford University), where the project was conceived and developed. CSLI still contributes some cost-sharing funds under the terms of the NSF grant.

[5] After we complete the task of programming the essential workflow-systems underlying the SEP, there will be less programming time required. However, if we are to keep up with changes in technology, programming time will always be necessary.

6 Future Challenges

Clearly then, the principal future challenge for the SEP is to find a source of income by which it can continue to be universally accessible. In this concluding section, we discuss this challenge, along with two others.

6.1 Funding Models

We will, of course, attempt to raise an endowment. Indeed, we plan to prepare grant proposals to foundations, asking them to give us money to hire a fund-raiser for a year, at full or half-time. But we anticipate that it could take up to 10 years to raise an endowment large enough to cover our operating costs.[6]

Our present focus, however, is to explore funding models intermediate between universal free access and full-fledged subscription models. For example, we plan to study the following two models, both of which might be adopted without incurring all of the problems outlines in Section 4.

1. *Voluntary Archive-Acquisition Program.* On this income-producing plan, the SEP would remain free to everyone, but institutions which subscribe to this program would be entitled to download and store our 4 quarterly archives each year they subscribe. (Those who choose not to pay would still be able to access all of our pages.) There would be 2 advantages to subscribing: (a) the institutions which subscribe would be entitled to serve their copies of the archives whenever our server and its mirror sites are down, and (b) should the SEP project ever cease to exist, these institutions would own, and be able to locally circulate, copies of our archives even though our servers are no longer active. For an extra fee, we could enhance this service by burning and distributing yearly CDs of the archives for that year.

2. *Archive-Access Program.* On this income-producing plan, *only* those institutions/users who pay a yearly subscription fee would be able to access our archives for that year. The SEP's dynamic entries (which are always changing) would still be available free to everyone. However, since citation can take place only to fixed, archived versions of

[6] Remember that if endowments are managed properly and make 8 to 10% a year, then approximately one-half of the 8 to 10% would be returned to the SEP and the remaining half of the 8-10% would be reinvested.

the entries, the motivation for joining this program would be clear to scholars and librarians. On this plan, we could again create the following levels of service: (a) for a basic yearly fee, users at subscribing institutions would receive web-based access to the archives on our server, (b) for a higher fee, the institution would obtain the right to download and store the archives, and (c) for an even higher, but still moderate, fee, we would burn and distribute CDs to the subscribers.

We plan to investigate these and other models by which income could be raised. They strike us as offering the best hope of raising money in a way that addresses the problems discussed in Section 4.

6.2 Institutional Home

The question of funding models is connected to the question, where is the best institutional home for the Encyclopedia? We believe that the SEP is better off in an academic environment than in the hands of a commercial or even non-profit publisher/publishing house. Normally there would be three good reasons for joining forces with a non-profit, university-based publisher, namely, that such a publisher would: (1) offer expertise in the business of producing publishable material, (2) offer a more stable institutional home, and (3) have the mechanism for marketing and collecting revenues for the materials it produces. We consider these in turn.

Expertise?

We are not aware of any non-profit publishers which have the kind of expertise which already resides with the SEP project. Since 1995, we have been perfecting our model for dynamic reference works which can be run on a low-cost basis. Grants from the NEH and NSF for 1998-2003 have given us the financial resources to program a workflow system which would compare, on the open market, to \$200,000 – \$300,000 off-the-shelf 'web content management' software systems. The Stanford Encyclopedia of Philosophy has been successful to date as a project designed, programmed, and run by academics (not specialists) who have acquired the tools necessary to make use of the power that computers, the Internet, and web-based technologies provide. In particular, the most highly technical positions required by our project, Unix system administration and

Perl/CGI programming, are filled by *academics* working part-time.

A More Stable Institutional Home?

Currently, the SEP is published at Stanford University's Center for the Study of Language and Information (CSLI), and the Stanford Philosophy Department serves as its Advisory Board. Our analysis suggests that the best institutional home for the SEP is an academic setting of this kind. Numerous reasons for this are readily apparent. An institution such as CSLI or an academic philosophy department would have a more intimate and direct concern for the academic excellence of the project and for safeguarding a resource for the profession. Such a concern might not be shared by a non-profit, university-based publisher, since traditionally they let titles go out of print. Moreover, academic setting of a philosophy department or research institute has a concern for educating its graduate students and graduate students could play various and vital roles in the SEP project.

Many graduate students in philosophy have a background in mathematics and computer science. They arrive at graduate school with enough knowledge about Unix, web servers, etc., to work on or consult for our project. Here are two ways in which these students can provide a steady stream of innovative ideas for the future of the project. First, as paid part-time members of the SEP staff. Graduate students would make excellent part-time staff. As such, they could (a) help subject editors plan and commission entries (thereby becoming known to distinguished members of the profession outside their home institution), (b) acquire and use HTML or XML skills and help the Encyclopedia with content mark-up, (c) acquire and use their knowledge of Unix and web-servers to help adminster the project (thereby preparing them to use those skills in their later academic life), and (d) work as office staff, handling correspondence with the authors and relieving the Principal Editor of routine tasks in the administration of the Encyclopedia.

Second, work on the SEP could be made part of the graduate curriculum. A philosophy department, without exploiting the graduate students in any way, could create a one-hour/week proseminar for all first year graduate students. Each week, the students would be required to read and report on one article from the SEP in their field or in a related field. In this way, graduate students would enhance their breadth and analytic

skills as philosophers, improve their writing skills by focusing on whether entries are well-written from a pedagogical point of view, and suggest ways to improve and/or update entries. They could bring their talents with web-based searching to identify whether any related material on the web should be linked into the entries they consider.

Finally, it is important to note that a research institute such as CSLI can be an important collaborator in this project. For instance, CSLI has researchers with expertise in linguistics, computation, data-mining, etc. It also has a highly-skilled technical staff, which can deal with any technical issues (such as those connected with server operation, backup, etc.) that might go beyond the expertise of a typical academic department.

Marketing and Income Collection?

Of course, if we can find a way to keep the SEP a free resource, then the fact that a publisher offers marketing and income collection becomes moot. However, as we have seen, we may be forced to adopt an operating model intermediate between that of keeping the Encyclopedia free and requiring universal subscription. Such models would require some marketing and income collection.

Basic marketing would not be problematic for the Philosophy Department and CSLI. When our NSF grant runs out in 2003, the SEP will have been on the Web as a *free* resource for 8 years. During our first 6 years, we have become well-known throughout the philosophical world (both academic and non-academic) and many thousands of individuals know about, read, and rely upon our pages. If our service were to be shut-off or restricted in some way, libraries and other institutions would certainly hear about it from their constituents. Moreover, most of our 500+ authors and 70 subject editors would notify the libraries at their own institutions. In addition, the fact that the SEP is a free resource means that there are thousands (if not tens of thousands) of links to our web pages. If we were to start charging subscriptions for access, these links would all end up in an *advertisement to subscribe*, as soon as anyone followed the link.

Income collection could also be easily accomplished, and could be done by using a university-based eCommerce center, such as the one at Stanford University.[7] These eCommerce centers can provide subscription services via the Web and can handle subscription payments for departments that

[7] See <http://www.stanford.edu/group/itss-ccs/project/ecommerce/>.

create journals or other publications for sale. These eCommerce centers are relatively inexpensive to use.

Finally, we should mention that if a more sophisticated system for marketing and income collection is required, an alliance with the *non-profit* Philosophy Documentation Center might be possible. Discussions to this effect have already taken place.

6.3 A Move to Newer Technologies?

The SEP was designed to run on proven, free technologies. Of course, since we began the project in 1995, some of these technologies are now "legacies". But, in many cases, we chose to use certain technologies over others because they made the most sense given our budgetary constraints. We did have to make compromises in some cases.

We use HTML rather than XML for entry markup. We do not use any heavy-duty 'application server technology', since performance is excellent with our Apache server and Perl/CGI scripts. We do not rely on any heavy-duty data-base technology (such as Oracle), because our main data base has (or will have) only 1,000 to 2,000 records, as opposed to hundreds of thousands of records. We don't rely on Java or Javascript, though our authors are free to use it in their entries if needed. We avoid frames on the main pages of the Encyclopedia, though we use them in the web interfaces.

Those who follow trends on the web, however, will know that this implementation is relatively 'low-tech'. But this low-tech approach does have several advantages. One is that the system can run on any PC running a free Unix-based operating system such as Linux or FreeBSD. Our low-tech approach also does not require that we purchase any licenses or require that we become dependent on any commercial software. Just as important is the advantage that both philosophers with limited computer savvy and expertise, and philosophers in other parts of the world where access to hi-tech or up-to-date computer systems may be limited, can participate in the collaborative production of our DRW.

In addition, the newer technologies always seem to increase the costs of production (they often require specialized personnel, for example), and until we are satisfied that the benefits outweigh the costs, we will exercise caution when considering the latest technologies. But eventually some of these newer technologies may supercede the older ones and the SEP

will have to make the needed adjustments, assuming it is in a financial position to do so.

The question we are asked most frequently is, when do we plan to adopt XML as a markup standard? XML is now highly touted as the markup language to use in web publications. As a markup language, XML offers some serious advantages over HTML. For one thing, the tags are constructed on the basis of the kinds of content that appear in a document. For example, in HTML, one would format book titles using the italicizing tags, such as <i>...</i> or .... But in XML, one could format book titles with the tag <booktitle>...</booktitle>. This would allow one to search of the SEP in more sophisticated ways. One could tell the search engine to search only keywords in the <booktitle> environment, whereas in HTML, there is no way for a search engine to distinguish a keyword found in a book title from one found in other italicized environments, such as emphasized text or foreign words and phrases.

Another advantage of XML is the promise of more sophisticated mathematical and logical formatting. HTML has only weak resources for formatting sophisticated mathematical and logical notation. There is some promise that MathML (a formatting language which is a special instance of XML), when supported by MathML-aware browsers, will give web publishers the ability to publish professional-looking mathematical and logical notation.

However, these virtues of XML come at a cost. The first and foremost of these is the fact that since XML is a more sophisticated markup language, the costs of production rise significantly when taking proper advantage of XML's extended capabilities. Currently, our authors provide us with nearly 'web ready' HTML documents, which they produce with freely available HTML-editing software.[8] Indeed, they are free to use any HTML-editor to compose their entries—we do not want to force all authors to have to learn and/or use the same composition software. Until XML-editing software tools become widely available and easily configurable, our authors will not be willing to spend extra time using all the new tags provided by XML to format their entries. (For example, authors will understandably be reluctant to familiarize themselves with

[8] It must be mentioned, however, that we always have to spend time to bring their documents into compliance with international standards (e.g., removing proprietary HTML formatting codes that the HTML-creation software introduces) and to make them consistent with our other entries.

all the special tags such as <booktitle> and use them in their entries.)

There may be some ways, however, to ameliorate these costs. Suppose, for example, that there was a free software application which the authors could use to help them to graphically and automatically format entries in XML without learning the new tags. For example, any time an author wanted to insert a new item into the Bibliography, such a piece of software would, in response to a click on an 'Add Bibliography Citation' menu item, pop-up a window containing all the relevant fields (book title, article title, author name, date, city, publisher, etc.) of a typical citation. When an author inserts the information into these fields, the software would then mark the information with the appropriate XML tags in the sourcefile. There is very little extra cost to the author, since they have to type in the information in the Bibliography citations anyway. Of course, such a piece of software would be expensive to design, produce, and support on the major computer platforms. But until such software is widely and freely available or the SEP has the financial resources to hire XML-markup specialists, the move to XML will be problematic.

There is also a second problem with XML, which has to do with the fact that our authors now have electronic access to their entries and can keep them up to date. As we mentioned much earlier, authors can use their browser to contact the SEP's server through a web interface. When they activate our 'Make Changes' function, their browser will divide up a private copy of the entry into sections, and for each section, display both the rendered HTML and an editing box to the HTML sourcefile. The author can then edit the HTML sourcefile and redraw the screen to see that the HTML is rendered correctly. It is not difficult for authors to read past the HTML formatting tags to edit the text they wish to change, or even add basic HTML formatting to their updated text.

But this procedure becomes more difficult in XML, and especially, MathML. XML sourcefiles are much more highly formatted than HTML sourcefiles. A simple equation such as $2^2 + x = 8$ requires numerous MathML formatting tags and it is much harder to read past these tags to find and edit the text. (MathML was designed with the idea that authors would never actually edit the sourcefile, but always edit the file through a graphical interface.) So a move to XML would make it more difficult for our authors to update their entries since the sourcefiles would become much more difficult to edit. Again, there may be a way to get around this through a Java-based applet/servlet system which presented authors, no

matter where they are located in the world, with a graphical editing interface to their XML sourcefiles. But such a Java applet/servlet combination is extremely difficult to program so that it works with all combinations of computer architectures, operating systems (and their different versions), web browsers (and their different versions), etc. The costs would be exorbitant for a project that hopes to keep costs to a minimum. It is doubtful that even a single full-time programmer could design, produce, maintain, and support such an application. Consequently, a premature move to XML would interfere with the ease of scholarly communication which the SEP now enjoys.

As one can see, then, there are many challenges facing the SEP. We have a system that works reasonably well now, and we are working now to put ourselves secure the SEP's future for the long-term.

A Solution to the Problem of Updating Encyclopedias

Eric M. Hammer and Edward N. Zalta*

Center for the Study of Language and Information
Stanford University
(ehammer,zalta)@csli.stanford.edu

Abstract: This paper describes a way of creating and maintaining a `dynamic encyclopedia', i.e., an encyclopedia whose entries can be improved and updated on a continual basis without requiring the production of an entire new edition. Such an encyclopedia is therefore responsive to new developments and new research. We discuss our implementation of a dynamic encyclopedia and the problems that we had to solve along the way. We also discuss ways of automating the administration of the encyclopedia.

Note: This paper appeared in *Computers and the Humanities* (Volume 31/1, 1997, pp. 47-60). It is reprinted here with permission from the publisher. You may also access the paper in both (compressed) Postscript and Adobe Acrobat (PDF) formats.

The greatest problem with encyclopedias is that they tend to go out of date. Various solutions to this problem have been tried. One is to produce new editions in rapid succession.* Another is to publish supplements or yearbooks on a regular basis.* Another is to publish the encyclopedia in loose-leaf format.* In this paper, we propose a solution to this problem, namely, a `dynamic' encyclopedia that is published on the Internet.* Unlike static encyclopedias (i.e., encyclopedias that will become fixed in print or on CD-ROM), the dynamic encyclopedia allows entries to be improved and refined, thereby becoming *responsive* to new research and advances in the field. Though there are Internet encyclopedias which are being updated on a regular basis, typically none of these projects gives the authors direct access to the material being published. However, we have developed a dynamic encyclopedia which gives the authors direct access to their entries and the means to update them whenever it is needed, and which does so without sacrificing the quality of the entries. In the effort to produce a dynamic encyclopedia of high quality, we discovered that numerous problems had to be solved and that routine editorial and administrational functions could be automated. By reporting on our project, we hope to facilitate the creation of such reference works in other fields.

Basic Description of Dynamic Encyclopedias

We have recently developed the Stanford Encyclopedia of Philosophy (URL = http://plato.stanford.edu/). The principal innovative feature of this dynamic encyclopedia is that authors have an ftp (`file transfer protocol') account on the multi-user computer that runs the encyclopedia's World Wide Web server. This feature not only enables the encyclopedia to become functional quickly, but also gives the authors of the entries the ability to revise, expand, and update their entries whenever needed.

Traditionally, encyclopedias have not been very responsive to new research and developments in the field--it is just too expensive to publish regularly new editions in a fixed medium such as print and CD-ROM. However, a dynamic encyclopedia simply *evolves* and quickly adapts to reflect advances in research. We believe that the process of updating individual entries never ceases, and that any encyclopedia which takes account of this fact will necessarily be more useful in the long run than those which don't.

Authors who have a strong interest in and commitment to the topics on which they write will be motivated to keep their entries abreast of the latest advances in research. Indeed, dynamic encyclopedias may speed up the dissemination of new ideas. Of course, there may come a time when an author wants to transfer responsibility for maintaining the entry to someone else. In such cases, there is the possibility of having multiple entries on a single topic, and this is one of the new possibilities that can be explored in a dynamic encyclopedia.

Here is how we implemented our dynamic encyclopedia. We connected a multi-user (UNIX) workstation to the Internet and installed a World Wide Web server. We then created a cover page, a table of contents, an editorial page, and a directory entitled *entries*. We recruited Editorial Board members for the job of identifying topics, soliciting authors, and reviewing the the entries and updates when they are received. Once an Editorial Board member decides on a topic and has found an author to write it, he or she passes on the information to the Editor of the encyclopedia, who creates an ftp account and home directory for the author on the workstation and then sends the author the information on how to ftp the entries and updates when they are ready. So when authors ftp an entry or an update to their home directory, it becomes part of the encyclopedia* and the Board member responsible for that entry is automatically notified. It is then his or her responsibility to evaluate the (modified) entry and notify the author of any changes that should be made.

The innovative features of a dynamic encyclopedia that has been organized on the above plan are:

1. It can be expanded indefinitely; there is no limit to its inclusiveness or size. New or previously

unrecognized topics within a given discipline can be included as they are discovered or judged to be important.
2. It eliminates the lag time between the writing and publication of the entries.
3. It eliminates many of the expenses of producing a printed document or CD-ROM: typesetting, copy-editing, printing, and distribution expenses are no longer necessary.
4. It can change in response to new technology as the latter develops, such as new tools, languages, and techniques.

In addition, statistics software for the encyclopedia can maintain logs of access to the encyclopedia, such as which sites users access it from, which entries they access most, which topics they search for, etc. Such information can help inform decisions about which additional entries to solicit, which authors to recruit to write them, etc.

An important motivating feature of using the Internet as a medium is that the encyclopedia can reach a wider audience than is possible with traditional academic journals and books. Because of this, we are recruiting authors capable of writing articles that are of interest not only to specialists.

Next Up Previous
Next: Computer Supported Collaborative Work **Up:** Introduction **Previous:** Introduction

Eric Hammer and Edward N. Zalta
Wed May 14 17:44:00 PDT 1997

Computer Supported Collaborative Work

Encyclopedias are, in some sense, a collaborative effort. It seems natural, therefore, to analyze the task of building a dynamic encyclopedia in terms of `computer supported collaborative work' (CSCW).* For example, since both the Editor and the author will have write access to an entry, the place on the disk where the entry is stored constitutes a `group workspace'.* Thus version control may seem necessary to prevent simultaneous editing by different `group members'.

Version control could prove useful on those rare occasions when the Editor, as opposed to the author, changes an entry to repair a typographical error or fix some problematic HTML code. Although the Editor will typically leave such tasks to the authors, there may be times when quick action by the Editor is necessary. On such occasions, authors and Editor could find themselves in the situation of attempting to modify the entry simultaneously. However, to avoid such conflicts, we instruct our authors to follow a protocol for revising their work, namely, to begin both by notifying the Editor of their intentions and by downloading the current version of their entry from the Encyclopedia. Such a procedure will prevent author and editor from overwriting each others modifications.*

Coauthored entries will obviously be highly collaborative, but these constitute only a very small percentage of the entries. If we ignore coauthored entries, it is striking that some of the distinguishing features of CSCW are absent. For example, no member of the group of authors requires information on the current status of the work being done by other group members.* Moreover, no member of the group of authors requires information about the *history* of other authors' collaborative activities. Nor do members of the group of authors require information about the process of collaboration (e.g., the roles and responsibilities of other members, and which group members fit into which roles).

These features of CSCW, however, do apply to the Editor, who requires information on the current status of the work by the authors, on aspects of the history of the authors' activities, and on the process of collaboration. In addition, members of the Board of Editors will need information about the history of the activities of those authors writing on topics under their editorial control; for example, a board member needs to know as soon as such an author has updated an entry. And, finally, if the encyclopedia project has the financial resources to maintain a large central staff, then such CSCW concepts as conferencing, bulletin boards, structured messaging, meeting schedulers, and organizational memory could play a role in the design of administrative procedures.

Since we are operating on a much smaller scale, these last CSCW concepts will play almost no role in what follows. The CSCW features that do apply will become features of the central administrative

control of the encyclopedia and can be managed by properly defined databases and updating procedures. Thus, the CSCW concept most relevant to our enterprise is `work flow management'. By analyzing the way in which the Encyclopedia would typically function (i.e., the sequence of tasks of the parties involved and the sequence of transactions among the parties), one can predict and address many of the problems that would affect the smooth operation of the Encyclopedia. These will be discussed in the next two sections. Even the choice of technologies was to some extent dictated by this analysis of work-flow. For example, we investigated SGML as a possible markup language for the Encyclopedia entries and we created a Document Type Definition for a typical encyclopedia entry (thereby defining tags that the authors would use to mark up their entries). Although SGML is superior in many respects, several factors prompted us to choose standard HTML, including (i) the availability of HTML editors and guides (which makes it easy for authors to produce entries in the proper format without extensive training), and (ii) the availability of good, free HTML search engines. Many other choices about the construction of the encyclopedia were made on the basis of such work-flow considerations.

It should be clear from our brief description that a dynamic encyclopedia poses very interesting questions concerning work-flow management. With adequate financial resources, a project of this type might consider buying, adapting, and/or modifying some off-the-shelf commercial workflow management system.* But few of the systems available seem to be designed to solve the specific problems of the dynamic encyclopedia concept that we wanted to implement. We therefore decided to develop our own solution to the problems of work-flow, one tailored to our specific needs. Having Unix and perl as resources, we have been able to address the special problems that arise in working out the idea of a dynamic encyclopedia.

Problems Facing Dynamic Encyclopedias

There are a number of problems that face the production of a dynamic encyclopedia. First and foremost is the problem of quality control. Whereas all encyclopedias face the problem of choosing high quality board members and authors and the problem of editing entries, the dynamic encyclopedia has the further problem of evaluating changes to entries because authors have the right to access and change their entries when the occasion arises. In a static encyclopedia, once board members and authors are chosen, there is a single further step of quality control which involves the careful editing of submitted entries, so that errors are not published in the fixed medium. In contrast, a dynamic encyclopedia needs a systematic method of evaluating both the new entries posted to the encyclopedia and the subsequent changes made to those entries.

Second, there are the problems involved in producing an electronic work, such as maintaining a uniform entry style and familiarizing authors with markup languages and electronic file transfer.

Third, there are the problems of automating routine editorial and administrative tasks so that the encyclopedia can be set-up and maintained without a large staff. For example, the following processes can be automated: creating accounts for the authors, sending them email about their accounts and the ftp commands they might need, monitoring changes in the content to entries, updating the table of contents, cross-referencing entries, modifying the email aliases (such as the list of the authors' email addresses), notifying the board members that entries for which they are responsible have been changed, etc.

Fourth, there are the issues of copyright. Who should own the copyright to individual entries? Who has the responsibility for obtaining permission to display photographs? What rights do the authors have over their entries? What rights does the encyclopedia have to republish entries in altered form?

Fifth, there are the problems of maintaining the encyclopedia. How often should authors be expected to update their entries? What happens when an author no longer wants to be responsible for updating his or her entry? How do we turn over an entry to a new author? Under what conditions should the encyclopedia allow multiple entries for a single topic?

Sixth, there are the problems of site security. How does one prevent authors or anyone else from gaining access to other parts of the encyclopedia. What if an article is accidentally deleted or damaged?

Finally, there are the issues of citation and digital preservation. How should people using the Encyclopedia cite the articles? What happens if the cited material is subsequently deleted when an author updates or modifies the entry? How will the Encyclopedia be preserved so that the material will always

be available for scholarly research in the same way that the citations to current and past encyclopedias are available?

Solutions to the Problems

Quality Control

Like other high-quality reference works, the authors of entries will be nominated and/or approved by a carefully selected board of editors and the entries themselves will be subject to critical evaluation. But given that the authors have the right to access and change their entries at will, the dynamic encyclopedia has the special problem of how to evaluate updates to entries. Our solution is to monitor changes to each entry and to notify both the Editor and the editorial board member responsible for that particular entry. When notified of a change, the Editor immediately verifies that the entry has not been accidentally or maliciously damaged. More importantly, however, we have written a script that will send out email notices to the relevant board member automatically, not only when the entry is first transferred to the encyclopedia, but also when any changes are made thereafter.* A problem with this procedure is that Board members will be notified even if there have been trivial modifications to entries. Though we have configured our script so that changes that the Editor makes to an entry (to fix typographical errors, HTML formatting errors, etc.) are not reported, we are planning to make our script `smarter', so that it reports to the Board member only significant changes to content made by the author.*

Given that entries in the dynamic encyclopedia can be modified, the authors can improve their entries not only in response to comments from the relevant Board member, but also in response to comments received from colleagues in the field. The latter may also be aware of relevant research not mentioned in the article. However, this introduces a controversial element, since commentators might not be satisfied by the modifications, if any, that authors make in response to their comments and may therefore write to the Editors to make their case. So the Editors and Board members of a dynamic encyclopedia must be prepared to moderate between authors and such commentators.

As a final resort, the Editors can always remove entries should the authors fail to respond to valid criticism, from whatever source.

Production

To solve the problems of production, we have created an annotated HTML sourcefile of a sample entry. The authors may use this sourcefile as a model, replacing its content with their own content.* We created a list of HTML manuals available on the World Wide Web and linked this list into the Editorial Information page of the Encyclopedia. For those authors with HTML experience, we created a empty *template* sourcefile defining the basic entry format, which they can download and simply fill in with their content. Recently, however, a wide variety of HTML-editors have become available and we have created

a special page containing links directly to the download archives containing these editors. So the simplest way for an author with no HTML experience to create an entry would be for him or her to first download Netscape Navigator Gold from the archive, download our HTML template from the Encyclopedia, load the template into Navigator Gold, and then complete their entry simply by selecting text that they have entered and using menu items provided by Navigator Gold to format the text automatically.

Instructions which explain these options are automatically sent to the authors when we set up their accounts. These instructions also explain to the authors how to ftp their entry to our machine and get them into webspace once they have created the HTML sourcefile for their entry and tested it locally on their own computer. We have organized the author accounts in such a way that files transferred into the author's home directory immediately become a part of the encyclopedia.*

Automation

We have automated many of the routine editorial tasks so that the encyclopedia can be administered without a large staff. We have written UNIX and perl scripts to do the following: create accounts for the authors (from keyboard input by the Editors), send the authors email about their account and the ftp commands they might need, take notice of newly submitted entries, monitor changes in the content to entries, manage the cross-referencing between encyclopedia entries by linking keywords of new entries to other entries, modify the email aliases such as `authors' (which contains a list of the email addresses of all the authors), and notify the board members that entries for which they are responsible have been changed. Here is a more detailed description of some of the scripts that have been written:

new-author script: This script will perform the system tasks necessary to add a new author to the encyclopedia. The script automatically sets up an account and home directory for the author with the proper access privileges (i.e., `write' privileges for the author and the editors only), updates the encyclopedia archives (databases with information about authors and their entries), and mails customized information to the author about how to prepare his or her entry, access his or her account, and transfer the new entry to the encyclopedia's machine.

asterisks script: When an entry is assigned but not yet written, the name of the entry in the table of contents is marked with an asterisk. The `asterisks' script notices when an author has ftp'd a new entry to the encyclopedia and then removes the asterisk from the table of contents.

modifications script: This script sends email on a regular schedule to the Editorial Board members indicating which entries have been modified on which date. It determines which Board member is in charge of the entry and updates that Board member's log file with the filename, author, and date the file was modified.

encyclopedia script: This script is a database manager. It extracts and modifies information in the encyclopedia's databases. Among the tasks it performs are: (a) provide information about an author, (b) provide information about a board member, (c) provide information about an entry, (d) list authors by

last name, (e) list keywords to be used for cross-referencing completed entries, (f) add a keyword to the database, (g) remove a keyword from the database, (h) list the entry associated with a keyword, and (i) list all keywords for a given entry.

keyword script: This script verifies and, if necessary, updates the keyword cross-referencing links between entries. When a new entry is submitted, the script notifies the Editor if the author has included keywords for which there are no entries in the table of contents. The Editor can then decide either to add the entry to the encyclopedia (or associate the keyword with an existing entry) or to remove the keyword. The script also verifies that keywords for which authors have included links are linked to the correct entries. Finally, any keyword references to the new entry in previously written entries are automatically linked to the new entry by the script.

It should be mentioned that the selection of keywords is, in the first instance, carried out by the members of the Board of Editors at the stage when they identify topics for inclusion in the Encyclopedia. Since each board member will be chosen for his or her expertise in a philosophy subspecialty, the selection of topics and their corresponding keywords will be driven initially by the perspective that the board members have on their fields. However, the authors will also determine and list the concepts that are essential to understanding the entry they have contributed. When there are discrepancies between the concepts listed by the author and the topics identified by the board member, it will be the job of the Editor to work with these individuals and find the best way to organize the Encyclopedia. These judgements cannot always be made *a priori* and the keyword script identifies when such judgements have to be made.

Copyright Protection

Authors are instructed to read the encyclopedia's copyright notice before transferring their entry to the encyclopedia. The transfer of their entry constitutes an implicit acceptance of the copyright terms stated. The notice has three parts:*

> *Copyright Notice*. Authors contributing an entry or entries to the *Stanford Encyclopedia of Philosophy* retain copyright to their entry or entries but grant to Stanford University and the Editor an exclusive license to publish their entry or entries on the Internet. All rights not expressly granted to the University and Editor are retained by the authors. Copyright of the *Stanford Encyclopedia of Philosophy* itself is held by Stanford University and the Editor. All rights are reserved. No part of the *Encyclopedia* (excluding individual contributions and works derived solely from those contributions, for which rights are reserved by the individual authors) may be reprinted, reproduced, stored, or utilized in any form, by any electronic, mechanical, or other means, now known or hereafter invented, including printing, photocopying, saving (on disk), broadcasting or recording, or in any information storage or retrieval system, other than for purposes of fair use, without written permission from the Editor.

While this part gives authors copyright over their entries, the authors in turn give Stanford University and the Editor an exclusive license to publish the entry on the Internet. Note that to view an entry, the web browser accessing it makes a complete copy of the entry somewhere in the user's machine. We are assuming that such copying of entries qualifies as fair use, and is not ruled out by this portion of the copyright notice.

> *Licensing Agreement*. By contributing to the *Stanford Encyclopedia of Philosophy* authors grant to Stanford University and the Editor a perpetual, exclusive, worldwide right to copy, distribute, transmit and publish their contribution on the Internet. The authors also grant to the University and Editor a perpetual, non-exclusive, worldwide right to copy, distribute, transmit and publish any and all derivative works prepared or modified by the Editor from the original contribution, in whole or in part, by any variety of methods on all types of publication and broadcast media, now known or hereafter invented. Authors also grant to Stanford University and the Editor a perpetual, non-exclusive, worldwide right to translate their contribution, as well as any modified or derivative works, into any and all languages for the same purposes of copying, distributing, transmitting and publishing their work.

This part gives the Editor a license to use and modify submitted entries. The license gives the Editor the exclusive right to publish the entry on the Internet, using whatever technology is currently available, and a non-exclusive right to publish the entry in other media. It also gives the Editor the right to publish portions of an entry. For example, if someone searches the encyclopedia, a search engine will return only those portions of an entry relevant to the search keyword(s). The Editor may also wish to include a portion of an entry in an advertisement for the encyclopedia or in a description of the encyclopedia. Finally, it gives the Editor the right to modify entries, for example, to add links in the sourcefile to other entries or change the way entries are formatted.

> *Statement of Liability*. By contributing to the Encyclopedia authors grant to Stanford University and the Editor immunity from all liability arising from their work. All authors are responsible for securing permission to use any copyrighted material, including graphics, quotations, and photographs, within their articles. The University and the Editor of the Encyclopedia therefore disclaim any and all responsibility for copyright violations and any other form of liability arising from the content of the Encyclopedia or from any material linked to the Encyclopedia.

Because authors have access to their entries, they could include copyrighted material in an entry without the Editor's knowledge. Moreover, there is an interval between the time when an entry is modified and the time when it is checked. This clause protects the encyclopedia and its Editors from any problems with entries arising from these situations.

Maintenance

Dynamic encyclopedias require infrequent but regular maintenance by the authors and Board members,

and require only moderate maintenance by the Editor. Once the Board and authors have been selected and the entries have been written, maintenance of the encyclopedia will primarily involve revisions by authors and examinations of the revisions by the board members. The Editor will only need to handle activities that are not automated, such as communicating with authors and the board concerning any problems that arise, troubleshooting the operation of the encyclopedia, and commissioning new entries as new concepts become important.

We suggest that authors update their entries at least once every year. When an author no longer wishes to maintain his or her entry, the Editors and author have several options. One is to leave it in the encyclopedia, indicating that no further revisions will be made. It may come to be of historical interest. The Editor will then have to commission another author to write a second entry on the same topic. A second option is to transfer maintenance of the original entry to someone else, with the details to be worked out between the original author and the new author.

Security

For the most part, the security problems of a dynamic encyclopedia are the usual security problems of system administration. We have given our authors an `ftp account' on our machine rather than setting up an anonymous ftp server.* So only authors and the Editor can submit or modify entries. Moreover, an author can only modify entries in his or her own home directory.

The only way to protect against malicious and unauthorized access to the machine is to back it up on a regular basis. This also protects the encyclopedia against machine failures. We back up our encyclopedia onto tape and also onto an external hard drive.* This external hard drive has been configured as a boot disk and contains all the system software necessary to run the Encyclopedia. In case the machine that runs the Encyclopedia experiences catastrophic failure, we can install the external hard drive into one of our backup UNIX workstations and reboot, a process that takes fifteen minutes.

Citation and Digital Preservation

We propose that citations to our Encyclopedia conform to the Modern Languages Association style for the citation of electronic sources. The `MLA-style' format for citation is:*

> Author's Lastname, Author's Firstname. "Title of Document." Title of Complete Work (if applicable). Version or File Number, if applicable. Document date or date of last revision (if different from access date). Protocol and address, access path or directories (date of access).

So, for example, a citation to our entry on Bertrand Russell, would look like this:

> Irvine, Andrew. "Bertrand Russell." *Stanford Encyclopedia of Philosophy*. January 28,

1997. http://plato.stanford.edu/entries/russell/ (October 12, 1997)

So that cited material does not disappear when entries are revised, we have decided to fix a quarterly edition of the Encyclopedia and store those editions online on a special `Archive Page' of the Encyclopedia. By checking and citing the most recent quarterly edition, one can be sure that the material being cited won't disappear. Thus, the citation to the entry on Bertrand Russell becomes:

> Irvine, Andrew. Bertrand Russell." *Stanford Encyclopedia of Philosophy*. Fall 1997 Edition. http://plato.stanford.edu/archives/fall1997/entries/russell/ (October 12, 1997)

We are currently exploring whether there are any other alternatives to fixing a quarterly edition.*

Long term preservation of digital information is a somewhat more global problem than secure backup. From the previous section, it should be clear that on any given day, there exist three copies of the Encyclopedia (one on the principal computer, one on external hard drive and one recoverable from the backup tapes).* We maintain an archive of the backup tapes of the Encyclopedia in a separate building. We also have several similar UNIX workstations in the lab housing the main Encyclopedia workstation and each of these computers could serve as a backup machine. As long as we maintain the present edition and past quarterly editions on 3 separate hardware devices (transferring the data to new technology as it becomes available) and follow the security measures outlined above (employing whatever new backup systems become available), we will have adequately safeguarded the material that appears in our Encyclopedia for scholarly research far into the future.

Conclusion

A dynamic encyclopedia following the above plan, therefore, needs the following administrative staff: an Editor, a computer consultant, and an Editorial Board. The Editor will coordinate the activities of the encyclopedia and maintain the encyclopedia's host machine. Maintenance of the host machine does require some general system administration skills, such as updating the httpd installation and search engines, preparing a sample entry that demonstrates entry style, and maintaining the authors' accounts. A computer consultant will write the scripts described above, oversee the technical development of the project, and apprise the Editor of new developments taking place on the Internet.* Though an advisory board is not necessary, we have one to help us choose the members of our Editorial Board. The Editorial Board will be responsible for soliciting qualified authors to write entries on appropriate topics, and also for evaluating the entries contributed by the authors they solicit.

With a larger budget and support staff, a complete `work-flow' analysis could be developed, which noted and recorded the various (kinds of) transactions between editor and authors and between editor and board member. The Encyclopedia database should keep track of more information about the state of an entry than ours does.* At some point, we plan to develop a program which automatically sends out notices when it is time for the author of a particular entry to update their entry or bibliography. No doubt there are other ways to automate administrative tasks, and when time and money permit, we plan to implement them.

Although we have designed our dynamic encyclopedia principally with an eye toward solving the update problem, such an encyclopedia has other advantages. One is that there are no constraints on the length or number of entries other than that imposed by disk space. This feature easily accommodates multiple entries on a single topic (each reflecting a separate perspective). Another advantage is ease of distribution. By distributing the encyclopedia over the World Wide Web, it becomes accessible to anyone with Internet access. A third advantage is that the pace at which the encyclopedia can be published is limited by the fastest rather the slowest authors. There is no longer a lag between the time the entry is sent to the Editors and the time the entry can be published. Finally, since entries can be improved over time, any biases they may reflect can be found and eliminated. Thus, our solution to the problem of updating encyclopedias also provides a solution to the problem of avoiding bias in encyclopedias.

...thereafter.

We have taken advantage of the UNIX `find' program; it is invoked in a script (`modifications') that runs each night and makes note of which entries have been changed in the past 24 hours. The `find' command is invoked with the following flags:

```
find entries -ctime -1 -name '*.html' -print
```

This causes `find' to print a list of all the HTML files in the `entries' directory that were altered in the last day. For each HTML file in the list, the `modifications' script then determines which Board member is responsible for the entry and places a time-stamped line in that Board member's log file (the log file is simply a list of entries along with the date they were modified and the author of the entry). On a fixed schedule, another script (`send-notifications') then sends the log file to the Board member in an email message. This notifies the Board member that he or she should evaluate the modified entries.

...server.

To be precise, we gave each author a login account with a home directory but made it impossible for the author to actually telnet, log on, and run processes on our machine. We did this by assigning a nonexistent UNIX shell `/bin/nosh' as their login shell. When an author ftp's to the machine, the ftp daemon checks to make sure that he or she has been assigned a login shell, but it doesn't require that the shell be a serviceable one. Thus, authors have ftp privileges to and from their home directories, but no login privileges, thereby reducing the load on our server and increasing security. Furthermore, each author's name not only serves to identify his or her home directory but also serves to identify a UNIX `group' (of users), of which only the author and the Editor are members. The author's home directory is assigned to this group, thus allowing only the author and the Editor write privileges to the author's home directory. Even if a password is stolen, at most one entry could be damaged.

Why Philosophy Needs A `Dynamic' Encyclopedia of Philosophy

John Perry and Edward N. Zalta
CSLI/Philosophy Department
Stanford University

Contents

Introduction

At the Center for the Study of Language and Information (CSLI), we have developed a solution to the problem of updating encyclopedias, namely, a `dynamic' encyclopedia that is published on the Internet. Unlike static encyclopedias (i.e., encyclopedias that will become fixed in print or on CD-ROM), a dynamic encyclopedia allows entries to be updated, thereby becoming *responsive* to new research and advances in the field. A dynamic encyclopedia gives the authors direct electronic access to their entries and the means to update them whenever it is needed, and it does this without compromising the quality of the entries. Whereas static encyclopedias must publish supplements or an entire new edition to become current, a dynamic encyclopedia simply *evolves* and quickly adapts to reflect advances in research. The process of updating an encyclopedia never ceases, and the very concept of a dynamic encyclopedia takes account of this fact.

The *Stanford Encyclopedia of Philosophy* is our working prototype of a dynamic encyclopedia. This prototype implements the technical specifications developed in the paper `A Solution to the Problem of Updating Encyclopedias', which was coauthored by Eric Hammer and Edward N. Zalta (*Computers and the Humanities*, Volume 31/1, 1997, pp. 47-60).

We are now working towards the goal of turning this working prototype into a *mature* dynamic encyclopedia that will be useful both to professional scholars and the general public. It will not be a `finished' product because dynamic encyclopedias are never finished. But within a few years, we will have refined the operation of this new and innovative kind of dynamic reference work so that it will continue to prove its worth far into the future. We believe that the principles upon which our

encyclopedia is based will contribute to a reconceptualization the nature of reference works for the age of the Internet.

Basic Description

To implement our dynamic encyclopedia, we connected a multi-user Unix workstation (plato.stanford.edu) to the Internet and installed a World Wide Web server. We then created a cover page, a table of contents, an editorial page, and a directory entitled *entries* accessible to the web server. We recruited (and are still recruiting) Editorial Board members for the job of identifying topics, soliciting authors, and reviewing the the entries and updates when they are received. These Board members have begun recruiting authors who have a strong interest in and commitment to the topics on which they write and who will be motivated to keep their entries abreast of the latest advances in research.

However, the innovative technical feature of our encyclopedia is that authors are given a "file-upload" account on plato.stanford.edu, i.e., the computer that runs the encyclopedia's World Wide Web server. Once an Editorial Board member decides on a topic and finds or approves an author to write it, he or she then forwards the information (via email) to the Editor of the encyclopedia, who then creates a file-upload account for the author on plato.stanford.edu and sends the author detailed information on how to prepare the entry and upload the entry (or update) when it is ready. When an author uploads an entry or an update (using a web browser) to his or her private directory on plato.stanford.edu, only the editorial staff can view it (they have password protected access). The Editorial Board member responsible for that entry is automatically notified that the entry has been put online or changed. The Board member then inspects the new material, and if he/she approves it, the new material is then published in public webspace; otherwise, the author is sent suggestions for improvements (and in some cases, the entries must be rejected and a new author must be commissioned).

Innovative Features

The most obvious innovative feature of an encyclopedia fitting this description is that it will not go out of date. When new ideas are published in books and journals of philosophy, the authors of our encyclopedia can summarize the ideas and update their entries. Since the encyclopedia will be accessible to web-browsers such as Netscape or Internet Explorer, a wide audience (academics, students, and the general public) may become informed of the latest advances in thought more quickly. We believe that this will speed up the dissemination of new philosophical ideas to a wide audience.

The other innovative features of a dynamic encyclopedia that has been organized on the above plan are:

1. The entries in a dynamic encyclopedia can be *improved* and *refined* over the course of time. As Board members and colleagues read the entry and give the author feedback, the author can enhance the article to make it more readable, make it more logical in form, repair typographical errors, etc.

2. The encyclopedia eliminates the often large span of time that appears between productions of large-scale `static' encyclopedias. The Macmillan *Encyclopedia of Philosophy* (edited by Paul Edwards) was published in 1967. The Routledge *Encyclopedia of Philosophy* (edited by Edward Craig) will come out in 1998. During the 30 year gap, no up-to-date full-scale encyclopedia has been available. In 2003, when the Routledge Encyclopedia starts to show a few signs of going out of date, ours will still be current. In 2008, the differences will be even more striking.
3. The encyclopedia eliminates the lag time between the writing and publication of the entries. There won't be the usual two year delay between the time the article is written and the time the encyclopedia is published. Some of the articles written for the forthcoming Routledge Encyclopedia will already be several years old when they appear in print in 1998.
4. The encyclopedia can be expanded indefinitely; there is no limit to its inclusiveness or size. New or previously unrecognized topics within a given discipline can be included as soon as they are discovered and judged to be important.
5. For certain controversial topics, the encyclopedia can include more than one entry on a single topic, each one representing a different point of view. This feature reduces the bias that affects other encyclopedias. The forthcoming Routledge Encyclopedia, by contrast, will contain just a single entry on each topic. Biases of the author may sometimes go unremarked and unsophisticated readers will be unaware of the alternative point of view. We are in a position to publish two or more entries on controversial topics in the philosophy of mind, medical ethics (euthanasia, abortion), political philosophy, etc.
6. Not only will the Bibliography sections be up to date when entries first come online (since there is no lag time between the writing and publication of the entry), but also, for the first time, encyclopedia entries can be accompanied by more comprehensive bibliographies. Print- and CD-ROM-based encyclopedias have a fixed amount of space to publish bibliographies and so the authors can list only a small number of first-rank articles in the field. Our authors can give a complete listing of first-rank articles and books. If the list proves to be overwhelming, they can further divide the list into first-rank articles and books that must be read and those that should be read. If the list of first-rank articles and books is not overwhelming, the author may develop a more inclusive bibliography. The bibliographies of our entries will therefore become *the* place to look for references to a given philosophical topic. We expect our authors to update their bibliography once a year.
7. The encyclopedia will have an *automatic* cross-referencing system. When new entries come online, the keywords in the section `Related Entries' will be automatically linked to the other entries in the Encyclopedia and the keyword in the other entries referring to the new entry will be linked to the new entry.
8. The encyclopedia will include not only internal links that cross-reference the entries, but each entry will contain *updatable* external links in a special section called `Other Internet Resources'. The authors may judge which other Internet sites are worthy of being linked into this section of their entry. For example, Andrew Irvine's entry on Bertrand Russell has both internal and external links. In the section `Other Internet Resources' in this entry, there are links to the online Russell Archives at McMaster University, the Bertrand Russell Society web page, the web page of the Bertrand Russell Editorial Project, etc. *These updatable links cannot be included in print- or CD-ROM-based encyclopedias,* much less be maintained and kept up to date. The entry on Russell in

the forthcoming Routledge Encyclopedia will lack such connections to these invaluable Internet resources!

9. The internet format avoids most of the expenses of production and distribution connected with a major reference work. It eliminates many of the expenses of producing a printed document or CD-ROM: typesetting, copy-editing, printing, and distribution expenses are no longer necessary. We provide authors with an HTML template so that they can easily typeset their entries in HTML using an HTML-editor such as Netscape Navigator Gold (there are now over 10 such HTML-editors on the market, many of which are free for academic use).(1) The editing will be done collaboratively by the editorial assistants, authors, board members, and Editor as a routine function of the quality control systems.
10. A dynamic encyclopedia can change in response to new technology as new tools and languages develop. For example, if Java becomes more widespread, Encyclopedia entries on neural nets, turing machines, prisoner's dilemmas, evolutionary game theory, etc., can include demonstrations and `applets' that the user of the Encyclopedia can download to learn interactively the concepts being discussed.
11. Statistics software can process the information in the access log of the encyclopedia web server and identify which sites users access it from, which entries they access most, *which topics they search for*, etc. Such information can help inform decisions about which entries to add, where to advertise, etc. This information is absolutely invaluable to the editors of an encyclopedia, and yet, no such access statistics can be maintained for static encyclopedias. Since numerous copies of static encyclopedias exist, there is no way to track the frequency individual entries are read. Our access log, which excludes the accesses by our own computers and recognizable WWW indexing worms, indicates that just in the period from September 15, 1996 to September 20, 1997, there were over 19,000 accesses from the U.S. educational (edu) domain, over 24,000 from the commercial (com) domain, over 1000 from the U.S. government (gov) domain, over 300 from the U.S. military (mil) domain, close to 20,000 from the network (net) domain, and over 1000 from the non-profit organization (org) domain (another 27,000 accesses were unresolved). These logs also show that during that same period, the Encyclopedia has been accessed from over 90 different countries, that Andrew Irvine's entry on Bertrand Russell has been accessed nearly 10,000 times, and that our encyclopedia has recently started to average over 8000 accesses per week. (See the Recent Access Statistics page (General Statistical Summary for the period of September 15, 1996 -- September 20, 1997), which is linked into the Editorial Information page of the Encyclopedia.)

No print or CD-ROM based edition of an encyclopedia has the above features and this includes the Routledge Encyclopedia forthcoming in 1998.

Future Significance

What is the future significance of this project, in the context of present availability of encyclopedias in philosophy? In 1998, we will see the publication of a major new reference work, the vast Routledge Encyclopedia of Philosophy. A new supplementary volume for 1967 Macmillan Encyclopedia was

released last year. At least ten other reference works in philosophy have been released recently.[(2)] It might seem, then, that the reference needs of philosophers are well-served, and that there is little need for the project of an online Encyclopedia of Philosophy.

This is not so, however. The last major, comprehensive encyclopedia before Routledge's was the 1967 Macmillan Encyclopedia. Even in a relatively slow moving field such as philosophy, 30 years is a long time to wait between encyclopedias. As fine as the Macmillan Encyclopedia was, by the time it was five years old, its value as a reference work for the philosophy profession had greatly diminished. By the mid to late 1970s, a student might go to an encyclopedia looking for information about the Kripke/Donnellan theory of reference, the Lewis and Armstrong identity theories of mind, Putnam's functionalist theory of mind, or Rawls's theory of justice and find nothing of value in the Macmillan Encyclopedia. So the philosophy community went for 20 -- 25 years before the recent handbooks and dictionaries attempted to fill the gap.

In this context, the Routledge Encyclopedia will be a welcome addition and a wonderful new tool. But within the next five to ten years, it too will be out of date, along with the other reference works in philosophy cited. There are more professional philosophers, more journals, more articles, more books than every before in history. There is much valuable and interesting work being done that will be cited in undergraduate classes long before another encyclopedia is due on the present thirty year cycle.

Moreover, the philosophy profession cannot be confident that there will ever be another major print encyclopedia. The Routledge encyclopedia represents an enormous investment. The cost of purchase is also enormous, about $2500 for the CD-ROM edition. Routledge will not be quick to replace it. And yet even the CD-ROM technology is already dated for reference tools. By contrast, the Internet is ideal for reference tools, but not ideal (as far as one can see at present) for traditional private print publishers to make money.

Those academic disciplines deemed more scientific and essential to national goals or business interests than philosophy will have many more ways to subsidize their reference needs. We believe a partnership between CSLI and the philosophy profession to develop an online philosophy encyclopedia represents the best chance for the profession not to be left behind and without adequate reference tools in the future.

Our online encyclopedia, by its nature, will never be `finished'. But we project that it will be mature, in the sense of having virtually all presently planned entries complete, in about four years. Within two years thereafter, its inventory of articles should be very close to that of the Routledge. That means our Encyclopedia will be available as a full-fledged alternative for philosophy students *at about the time* that the Routledge encyclopedia begins to show signs of age, and at a time when students will increasingly be familiar with the web and expect to use it for reference work. Because of the fact that our Encyclopedia is `alive', it will stay current.

Thus, we propose not to redo the work that has already been done for the Routledge Encyclopedia, but to to use new technology to begin working on the next generation of reference tools for philosophers and

their students.

Funding the Encyclopedia

Most of the effort that goes into the creation and maintenance of the Encyclopedia will be donated by those who welcome the opportunity to advance the serious study of their favorite topics and figures. Our plan is that the authors, the Board of Editors and the Advisory Board will be unpaid (unless the Encyclopedia resolves its funding problems). For the foreseeable future, CSLI will provide an office for the Encyclopedia staff and computer, backup systems, and cover other indirect costs. If in the future CSLI goes out of existence or is unable to provide this support, it seems likely some other institution could be found that would do so, either here at Stanford or on some other campus. The amount of space and computer power are not that great, by the standards of late twentieth century American academia.

However, we do not believe the Encyclopedia can function on a completely volunteer basis. At a minimum, we must pay for a part-time Editor, part-time editorial assistants and at least one part-time computer programmer. Some equipment and supplies have to be purchased and telephone and other services (e.g., networking) need to be paid for. We estimate costs as follows:

1. Staff Salaries: $100,000
2. Staff Benefits: $25,000
3. Supplies, equipment, services, etc.: $25,000

----

4. Total: $150,000

Print encyclopedias are funded by sales to individual and institutional users. Our hope is our dynamic encyclopedia will remain free to all individual users. There should be as few obstacles to the serious study of philosophy as possible. We hope that the online encyclopedia will be available to anyone anywhere with access to the net.

The institutions most closely associated with users include Philosophy departments, universities (and their libraries), and professional organizations for philosophers (such as the APA, CPA, AAP, etc.). Universities should be able, in the long run, to support online encyclopedias and other online resource materials from the same budget lines used for print materials that now serve these purposes. One strategy for funding the Encyclopedia would be to charge university libraries a nominal yearly access (subscription) fee. This subscription fee would give computers based at those universities the right to access the Encyclopedia. If 1000 universities each pay $150/year for unrestricted access to the Encyclopedia, the Encyclopedia's projected annual budget would be covered. The $150/year access fee could simply represent an average---the fee could be set so that universities with larger (smaller) budgets or student populations pay a proportionally larger (smaller) access fee. This would keep the Encyclopedia free to the public.

However, in the short run, we do not expect to be able to tap these resources. Our Encyclopedia won't be

mature for another 3 - 5 years. Right now, we want University libraries to use their funds to purchase the much anticipated Routledge Encyclopedia. Until our encyclopedia has matured, we will need to look elsewhere for support.

We feel that Philosophy departments and professional organizations are natural sources of funding. Philosophy departments differ enormously in the amount of discretionary funds available to them, with the mean amount extremely low. Some departments do have such funds, however, and a few hundred dollars from a number of such departments could help significantly. However, we prefer not to approach individual departments until there is mature product that will be useful to them. (We might make an exception for a number of the most well-endowed departments, some of which are represented on our Editorial Board.) At the startup phase, it seems more appropriate to approach those institutions part of whose mission, or enlightened self-interest, is to help projects like this get off the ground. Within philosophy, this means professional organizations like the APA. At this point, the Pacific APA and the CPA have made generous contributions, and we have approached the Central and Eastern APA. Of course, a commitment at the national level would be preferable.

Among the funding sources that are not directly connected to Encyclopedia users, we distinguish between government sources, foundations, and businesses. We have received a 2-year grant from the NEH. They will give us $120,000 to develop the Encyclopedia, to be delivered over two years (AY 1998-99 and 1999-2000). We will apply for an NSF grant through the Digital Libraries II initiative. If this proposal proves successful, this would take care of our funding needs until 2003, at which point the Encyclopedia will be close to maturity.

We are just beginning to solicit funds from appropriate foundations. The development and fund-raising staffs at CSLI and Stanford are being most helpful in this respect.

It seems to us that Netscape, Microsoft, Yahoo, and other companies with a stake in the future of the Internet might have multiple reasons for investing in our Encyclopedia. In this regard, it would be very helpful to discover philosophers within such companies who would be willing to help us identify and approach the relevant people with funding authority.

(Some of these companies have been indirectly funding the Encyclopedia for the past two years through CSLI's Industrial Affiliates program. CSLI was founded in 1983 with a grant from the Systems Development Foundation. These funds were exhausted long ago. Since 1993, the Industrial Affiliates program has been the principal source of CSLI's operating budget.)

A final possibility for money from the private sector is advertising. One can imagine tasteful and wholly appropriate links from the Encyclopedia home page to the websites of publishers of philosophy books. Whether these publishers will find this to be a economical use of their advertising budgets remains to be seen.

We would welcome comments from the APA membership on any aspect of fund-raising. Anything from

leads concerning fund-raising in industry to comments about the appropriateness of advertising would be welcome.

Footnotes

1. When using such HTML-editors, the author simply selects (highlights) text and then uses `menu' functions to format the text in various ways (such as to italicize, to put the text in a list environment, to create a link and use the text as the label on that link, etc). The HTML-editor then creates the appropriate HTML code in the underlying HTML file. (return to text)

2. The list includes: *A Companion to the Philosophy of Language* (Blackwell, 1997), *Companion Encyclopedia of Asian Philosophy* (Routledge, 1997), *Routledge History of Philosophy* (Routledge, 1997), *Oxford Dictionary of Philosophy* (Oxford University Press, 1996), *Blackwell Companion to Philosophy* (Blackwell, 1996), *Biographical Dictionary of Twentieth Century Philosophers* (Routledge, 1995), *Cambridge Dictionary of Philosophy* (Cambridge University Press, 1995), *Oxford Companion to Philosophy* (Oxford University Press, 1995), *A Companion to Metaphysics* (Blackwell, 1995), *A Companion to Epistemology* (Blackwell, 1992), *A Companion to the Philosophy of Mind* (Blackwell, 1994), and *Handbook on Metaphysics and Ontology* (Philosophia Verlag, 1991). Stanford Encyclopedia of Philosophy: A Dynamic Reference Work

Edward N. Zalta[*], Colin Allen[†], Uri Nodelman[*]
[*]Stanford University and [†]Texas A&M University
zalta@stanford.edu, colin›allen@tamu.edu, nodelman@stanford.edu

The primary goal of the Stanford Encyclopedia of Philosophy project <http://plato.stanford.edu/> is to produce an authoritative and comprehensive reference work devoted to the academic discipline of philosophy that will be kept up to date *dynamically* so as to remain useful to those in academia *and* the general public. To accomplish this goal we have designed and implemented web-based software by which academic philosophers can collaboratively write and maintain such a 'dynamic reference work'. Our implementation has features that are not found in any other online reference work in any discipline, and that enable the profession of philosophy to maintain such a reference work without the cost or level of staff support required for traditional reference work publishing.

A *dynamic reference work* is a new concept in digital libraries technology. We define this concept as follows: (1) it is published in a continuously revisable electronic medium, (2) it offers a comprehensive set of entries on topics in a target discipline, (3) it *provides the authors of the entries with electronic access* to the reference work's central web server, so that they can remotely edit and update private copies of their entries and submit them for publication according to a regular update schedule and at any other time it becomes necessary to revise, (4) it maintains quality by way of a distinguished Board of Editors, the members of which commission the entries and referee both the initial versions of the entries and subsequent substantive modifications, *prior to publication* on the web, and (5) it creates, and makes publicly available, archives of the entries on at least a quarterly basis (i.e., these contain fixed versions of the entries, which can be cited in scholarly publications). A dynamic reference work based on this model constantly evolves and becomes *responsive* to new research.

Clauses (3) and (4) of this definition indicate that a *dynamic* reference work is not merely a revisable reference work or one that is published online. Successful implementation of the dynamic aspects of this definition depend upon the ease with which the authors, subject editors, and the principal editor have access to the tools and information that allow entries at all stages of the work flow to be managed asynchronously. In such an environment, each entry has its own deadlines and it is necessary to track electronically the location of every entry in the work flow and provide automated reminders to individuals with work pending. Our success in organizing 75 distinguished editorial board members to oversee 450 expert authors, working to a set of deadlines specified by our work flow, distinguishes our project from other, less formal, on-line encyclopedia projects.

We will demonstrate how our password-protected web interfaces and our back-end processing system and workflow system work together to facilitate this collaborative effort. Our system has several unique features designed to simplify the collaborative production of a dynamic reference work including tools for web-based editing of html source and side-by-side comparison of file versions. The web interface for authors allows them to: (1) download our templates and style sheets, (2) to upload their new entries into a private area of our web server, (3) to remotely edit copies of their entries which are stored in this private area, and (4) to submit their entries for editorial review. The web interface for subject editors allows them to: (1) add important or new topics in philosophy to our database, (2) commission authors to write entries, (3) examine and comment on the new or revised entries submitted by the authors prior to publication, (4) display, in their web browser, revised and original entries side-by-side, *with the differences highlighted*, and (5) accept or reject entries and revisions. The principal editor has a web interface, by which this collaborative workflow system is administered. Among other things, it tracks deadlines for each stage of the publication and revision process for each entry.

We have designed our software in such a way that authors and subject editors require only basic computer skills to participate effectively in the project. Authors may also use any html-authoring software to create their entries, which then are automatically formatted by our software and may be easily maintained by authors through the web interface. (This author-friendliness is an advantage of our html-based system over currently available xml-based alternatives.) Our use of cgi scripts also means that our browser-based interfaces are accessible from any internet-connected workstation without the installation of any special software. Thus the system enables an international collection of authors and subject editors to solicit, submit, review, revise, publish, and update high quality articles under the guidance of a principal editor, with minimal support from a programmer and other staff.

The technical specifications of our system are described in the project description of our NSF/DLI-2 proposal (accepted in August 2000), which may be found at the URL: <http://plato.stanford.edu/NSF/project-description.pdf>

This research is supported by NSF grant #IIS-9981549.

CURRICULUM VITAE

ALASDAIR IAN FENTON URQUHART
Professor of Philosophy
University of Toronto
Date of latest revision: April 1998

A. Biographical Information

Personal
Date of Birth: 20 December, 1945

Citizenship: British (Landed Immigrant 1970)

Home address: 54 Boustead Avenue, Toronto, Ontario, M6R 1Y9

Home phone: 767-5240 (unlisted)

University address: Department of Philosophy, University of Toronto,

215 Huron Street, Toronto, Ontario M5S 1A1

Office phone: 978-6789

Degrees

M.A. Hons., University of Edinburgh, 1967

M.A. University of Pittsburgh, 1969

Ph.D. University of Pittsburgh, 1973

Title of Ph.D.Thesis: "The Semantics of Entailment"

Supervisors: Profs. Nuel D. Belnap Jr. and Alan Ross Anderson

Employment

Present Appointment

Professor, University of Toronto, 1986 -

Associate Professor, University of Toronto, Erindale College, 1975-86

Date of appointment to Graduate School, 1973

Date of tenure award, Spring, 1975

Assistant Professor, University of Toronto, Erindale College, 1973-75

Lecturer, University of Toronto, Erindale College, 1970-73

Teaching Fellow, University of Pittsburgh, 1967-70

Professional Affiliations and Activities

Consulting editor Journal of Symbolic Logic 1983-89

Former editor of Canadian Philosophical Monographs

Associate of the Institute for the History and Philosophy of Science and Technology

Referee for Canada Council, NSERC, NSF etc.

Referee for JSL, JPL, Studia Logica etc. etc.

Member, Executive Committee, Association for Symbolic Logic 1987-90 Member, Advisory Editorial board, Studia Logica 1991- Member, ASL committee on meetings in N. America 1992- Member, ASL nominating committee, 1993 -

Programme comittee, joint meeting of ASL and SEP, York University May 1993.

Board of consultant editors, Russell. Editor, Lecture Notes in Logic (Springer Verlag), 1994-

Editor, Trends in Logic, 1994-

Consulting editor, Studia Logica.

Member of editorial board, International Studies in the Philosophy of Science.

Editor for non-classical logics, Stanford On-Line Encyclopedia.

B. Academic History

a. Research Endeavours

Non-classical logics, lattice theory, philosophy of logic, foundations of mathematics, history of logic, theory of computation, computational complexity theory.

b. Research Awards

Canada Council Leave Fellowship 1976-77 (one-year) - $9,200.
SSHRC Leave Fellowship 1983-84 $11,500.
SSHRC Research Grant 1984-85. Project: ``Investigations in logic" $6,920.
SSHRC Research Grant 1986-87. Project: "Studies in Complexity Theory", $10,185.
SSHRC Research Grant 1986-87. Project: "Editing Volume 4 of Bertrand Russell's Papers", $45,615.
SSHRC Research Grant 1989-91. Project: "Editing Volume 4 of The Collected Papers of Bertrand Russell", $124,700.
SSHRC Research Grant 1991-2. Project: "Editing Volume 4 of the Collected Papers of Bertrand Russell." $46,490.
SSHRC Research Grant 1992-3. Project: "Editing Volume 4 of the Collected Papers of Bertrand Russell." $10,400.
NSERC Operating Grant 1991-4. $24,000 p.a.
NSERC Operating Grant 1994-8. $27,000 p.a.

``Beth's definability theorem in relevant logics,'' forthcoming in Festschrift for Helena Rasiowa.

b. Books and Chapters in books

Temporal Logic (joint author with Nicholas Rescher), Springer Verlag New York and Vienna 1971.
Section on Many Valued Logic in Gabbay and Guenthner (eds.), Handbook of Philosophical Logic, Vol. III. Reidel l984.
Sections 47 and 65 of Entailment, Vol. 2, by Anderson, Belnap and Dunn. Princeton University Press 1992.
The Collected Papers of Bertrand Russell, Volume 4 : Foundations of Logic 1903-05 (Editor).
``Zeit und Zeitlogik'' (co-author Nicholas Rescher), in Zustand und Ereignis, ed. by Bertram Kienzle, Suhrkamp 1994 (partial translation of Temporal Logic).

Non-refereed Publications

a. Articles

About 100 short reviews on papers in logic and mathematics Mathematical Reviews, 1973-85.
Review of The Paradox of the Liar, ed. by Robert Martin, Dialogue, Vol. 10, (1971), pp. 823-825.
Review of The Development of Mathematical logic, by R.L. Goodstein, Historia Mathematica, Vol. 11, pp. 212-214.
Review of Distributive Lattices, by Balbes and Dwinger, Journal of Symbolic logic, 40 (1975).
Review of Classical Propositional Operators, by Krister Segerberg, Canadian Philosophical Review, Vol. III, No. 6.
``Intensional Languages via Nominalisation'', Pacific Journal of Philosophy, 1981.
Review of Mathematics in Philosophy, by Charles Parsons, History and Philosophy of Logic, (1985).
Review of two papers on symbolic logic, JSL 1985.
Review of Routley et al. "Relevant Logics and their Rivals I" Studia Logica (1988).
Review of Rachel Garden "Modern Logic and quantum mechanics", Journal of Symbolic Logic, Vol. 53, 648.
Review of J.M. Dunn, J. of Symbolic Logic, Vol. 54 (1989), pp. 615-16.
``Russell's zigzag path to the ramified theory of types'', Russell, N.S. Vol. 8 (1988), pp. 82-91.
Review of Troelstra and van Dalen "Constructivism in Mathematics Volume 1", Studia Logica 1989.
Review of Troelstra and van Dalen "Constructivism in Mathematics" Volume 2, Studia Logica, June 1991.
Review of Per Martin-Lof "Intuitionistic Type Theory", Studia Logica 1990.
Review of Stephen Read "Relevant Logic", History and Philosophy of Logic, Vol. 11 98-99.
Review of Jon Barwise "The situation in logic", Can. Phil. Rev., Vol. X, 96-8.
Review of Stuart Shapiro "Intensional Mathematics", Studia Logica, April 1990.
Review of paper by D. Deutsch, J. Symbolic Logic, Vol. 55, 1309-10.
``Functional interpretations of feasibly constructive arithmetic'' (extended abstract) in Feasible Mathematics,ed. Buss and Scott, Birkhauser 1990, 97-8.

Review of Hermes No. 7 , in Russell, Vol. 11 (1991), 103-5.
Review of M. Detlefsen, "Proof and Knowledge in Mathematics", Canadian Phil. Reviews, Vol. 12 (1992), 237-8.
Review of Rodriguez-Consuegra, "The Mathematical Philosophy of Bertrand Russell", Philosophia Mathematica Vol. 1 (1993), 90-93.
Review of Hartry Field "Realism, mathematics and modality", History and Philosophy of Logic, Vol. 14 (1993), 117-119.
Review of "Lectures on Linear Logic" by Anne Troelstra, Can. Phil. Reviews, Vol. 13, 126-128.
Review of "Russell's Idealist Apprenticeship" by Nicholas Griffin, Russell, Vol. 13, 104-108.
Review of "Substructural Logics", History and Philosophy of Logic, Vol. 16 (1995), 138-9.
Review of G. Malinowski, "Many-valued logics", Notre Dame Journal of Formal Logic, Vol. 35, 469-70.
Review of "Russell and Analytic Philosophy," J. Symbolic Logic, Vol. 61, 1391-2.
Review of "Feasible Mathematics II," J. of the I.G.P.L. Vol. 5, 301-2.
Review of Jagdish Mehra, "The Beat of a Different Drummer," International Studies in the Philosophy of Science, Vol. 11 (1997), 311-313.

Manuscripts in preparation and submitted

``Weakly additive operators in distributive lattices", in preparation.
``The symmetry rule in propositional logic," submitted.
``The graph constructions of Hajós and Ore," submitted.

Papers presented at Meetings and Symposia

``A general theory of implication", Association for Symbolic Logic Annual Meeting, December 1971, New York.
``Free Heyting Algebras", Association for Symbolic Logic Annual Meeting, Dallas, January 1973.
``Implicational formulas in intuitionistic logic", Association of Symbolic Logic Annual Meeting, Atlanta, December 1973.
``Elementary classes in infinitary logic", Association for Symbolic Logic, Spring Meeting, Chicago, April 1975.
``A representation theory for lattices", Universal Algebra Conference, Oberwolfach, West Germany, August l976.
``Congruence latices and Heyting algebras", Universal Algebra Conference, Esztergom, Hungary, July 1977.
``Ockham lattices", Canadian Mathematical Society Annual Meeting, Calgary, December 1977.
``Equational classes of distributive double p-algebras", read to American Mathematical Society special

session on Varieties, Claremont, California, October 1978.
``Projective distributive p-lattices'', American Mathematical Society session on Universal Algebra, Boulder, Colorado, March 1979.
``Word problems for distributive lattice-ordered semigroups'' Charleston Conference on Universal Algebra, July 1984.
Talks to graduate forum (Philosophy) Fall 1982 and Fall 1983 on logic.
``How do we know mathematical proofs are correct?'', talk to IHPST October 31, 1985.
``The complexity of decision procedures in relevant logic'', presented at meeting of the Association for Symbolic Logic, Los Angeles, January 1989.
``Are there absolutely undecidable mathematical propositions?'' Talk to graduate forum, October 19 1989.

Invited Lectures

``What is Relevant Implication?'', International Conference on Relevance Logics, St. Louis, September 1974.
``How to put Routley and Meyer into a Comer'', University of Waterloo Conference on the Foundations of Logic, April 1982.
``Undecidability of Relevant Implication'', Wollongong, Australia, July 1982.
``Does Many-valued Logic make Sense?'', University of Melbourne, July 1982.
``The Undecidability of Entailment and Relevant implication'', University of Western Ontario, November 1982, also University of Buffalo, February, 1983, University of Alberta, February 1984.
``Russell's Zig-Zag Path to the Ramified Theory of Types'', Conference on Russell's Early Philosophy, University of Toronto, Summer 1984.
``Intensional Languages via Nominalization'', Society for Exact Philosophy, Halifax 1980.
``The Algebra of Entailment'', Asilomar conference on algebra and logic, July 1987.
``The Geometry of Entailment'', Indiana University, 12 November 1987.
``Complexity of Proofs in Propositional Logic'', Indiana University, 13 November 1987.
``Functional Interpretations of Feasible Arithmetic'', U. Pennsylvania, Mathematics Department, 7 December, 1987
``Functional Interpretations of Fesibly Constructive Arithmetic'', Conference on Feasible Mathematics, Cornell, June, 1989.
``Translation Problems in Modal Logic'', Society for Exact Philosophy, Edmonton, Alberta, August 1989.
``The complexity of propositional proof systems'', Berkeley conference on Logic from Computer Science, MSRI, November 1989.
``Failure of interpolation in relevant logics'', Kleene '90, Chaika, Bulgaria, July 1990.
``Complexity of proofs in classical propositional calculus'', Department of Mathematics, University of Waterloo, October 30 1990.
``Recent results in propositional complexity'', Dept. of Mathematics, McMaster University March 25 1991.
``Why are some tautologies harder to prove than others?'' Society for Exact Philosophy, Victoria B.C. May 1991.

``Russellian Propositions'' (co-author Judy Pelham), Conference on Logic, Methodology and Philosophy of Science, Uppsala, Sweden, August 1991.
``Russellian Propositions'' (co-author Judy Pelham), U. of Buffalo Logic Colloquium October 1991.
"Propositional Complexity", Talk to Mathematics Seminar, U. of Buffalo, October 1991.
"Complexity of decision procedures in relevant logic", McGill University Mathematics Seminar November 1991.
"The complexity of the Hajos calculus", "Mathematische Logik", Mathematisches Forschungsinstitut Oberwolfach April 14 1992.
"Complexity of the Hajos construction", logic workshop, U. of Victoria, B.C. July 3 1992.
"Recent results and open problems in classical propositional logic", Association for Symbolic Logic Annual Meeting March 13 1993, Notre Dame, Indiana.
"Recent work in complexity theory", talk to Logic and Philosophy of Science group, Toronto February 1994.
"Recent results in classical propositional logic", talk to Toronto Set Theory seminar, April 6 1994.
"Complexity of propositional proofs", invited lecture, Conference on Computational Logic, Indianapolis, October 14 1994.
``Russell and the Foundations of Logic 1903-05,'' invited lecture, Annual Meeting, Association for Symbolic Logic, Irvine, California April 2 1995.
Lectures on propositional proof complexity, DIMACS Workshop on Feasible Mathematics and Proof complexity, Rutgers University, Center for Discrete Mathematics and Theoretical Computer Science, August 21-25 1995.
``The symmetry rule in propositional logic,'' conference on the satisfiability problem, Siena, Italy, April 29 - May 3 1996.
``The graph constructions of Hajós and Ore,'' talk to the University of Toronto combinatorics seminar October 12 1996.
``Complexity of Propositional Proofs,'' talk to Philosophy Department Carnegie Mellon University, April 12 1997.
``Solution of a 2000-year-old logic problem,'' Philosophy Department, University of Waterloo, November 14 1997.
``Is Gödel's Theorem a red herring?'' Talk to the University of Toronto Cognitive Science and Artificial Intelligence Students' Association, January 15 1998.

D. List of courses (in preceding 5 years)

a. Undergraduate courses taught

PHL 245: Modern Symbolic Logic

PHL 246: Probability and inductive logic PHL 345: Intermediate Logic PHL 346: Philosophy of Logic

and Mathemataics

PHL 349: Set Theory PHL 342: Minds and Machines PHL 350: Philosophy of Language PHL 231: Existence and Reality PHL 344: Metalogic

b. Graduate courses taught

PHL 2121: Modern Logic PHL 2124: Seminar in Logic (theory of entailment) PHL 2124: Seminar in Logic (algebraic logic) PHL 2087: Russell PHL 2126: Foundations of Mathematics

PHL 2122: Advanced Logic (Seminar on Russellian propositions) PHL 2192: Frege

c. Theses Supervised

Masters Student:
Giovanni Panti (Mathematics) 1990.
David McClurkin (Computer Science) 1991.
Oliver Schulte (Computer Science).
Francois Pitt (Computer Science).
Doctoral Students:
Gerald Charlwood. Thesis topic: Relevance Logic. Period of supervision: 1974-78. Thesis completed 1978. Primary supervisor
Pamela Ely. Thesis topic: Medieval Logic. Period of supervision: 1975-80. Thesis completed 1980. Secondary supervisor.
Merrie Bergmann. Thesis topic: Metaphysics. Period of supervision: 1975-77. Secondary supervisor.
Ben Russell. Thesis topic: Wittgenstein's Philosophy. Period of supervision: 1978-80. Completion date: 1980. Secondary supervisor.
Mark Vorobej. Thesis topic: Deontic Logic. Period of supervision: 1979-83. Primary supervisor.
Alejandro Garciadiego. Thesis topic: History of Foundations of Mathematics. Period of supervision: 1978-1980. Secondary supervisor.
Peter Turney. Thesis topic: Inductive Inference and Stability. Thesis completed 1988. Primary supervisor.
Arnold Silverberg. Thesis topic: Anti-Realism in Semantics and Logic. Thesis completed 1988. Primary supervisor.
Andre Vellino. Thesis topic: The complexity of automated reasoning. Thesis completed 1989. Primary supervisor.

Judith Pelham. Thesis topic: Russell on propositions and objects. Thesis completed September 1993. Primary supervisor.
Kent Peacock. Thesis topic: Space-time view of non-locality. Secondarysupervision.
Andrew Malton (Computer Science Dept). Thesis topic: Functional Interpretation of Programming Methods. Secondary supervision.
Arvind Gupta (Computer Science Dept). Thesis topic: Constructivity in Tree Minors. Secondary supervision.
Frederic Portoraro. Thesis Topic: Automated theorem proving. Primary supervisor.
Xudong Fu (Computer Science). Thesis topic: Complexity of propositional proofs. Secondary supervision. Thesis completed February 1996.
Jeffrey Denson (Philosophy). Thesis topic: Objectivity in Frege. Primary supervisor. Withdrew from doctoral program 1995.
Arnold Rosenbloom (Computer Science). Secondary supervisor.
Achille Varzi (Philosophy). Secondary supervision. Thesis topic: General semantics. Thesis completed: October 1994.
Francois Pitt (Computer Science). Secondary supervision. Thesis topic: "Bounded arithmetic."
Anthony Jenkins. "The Nature of Logical Inquiry." Primary supervision.
C.K. Poon (Computer Science). Thesis topic: "The Complexityof the st-connectivity problem." PhD completed August 1995.
David Mitchell (Computer Science). Thesis topic: "Propositional Satisfiability Testing." Secondary supervision.
Tomoyuki Yamakami (Computer Science). Thesis topic: "Structure of average case hierarchies." Secondary supervision. PhD completed February 1997.
David Hyder (Philosophy). Thesis topic: "Helmholtz and Wittgenstein." PhD completed December 1996. Secondary supervision.

Administrative Positions

1970-72 Scholarships and Awards Committee, Erindale College

1973-74, 1974-75 Search Committee

1974-75, 1977-80 Personnel Committee 1978-79 Discipline Representative, Erindale College

1980-83 UTFA Representative

1979 Tenure Committee 1980 Promotion Committee

Served on thesis committee, James Hoover, Department of Computer Science.

Wrote internal appraisal for Tom Archibald (IHPST, May 1987) Ph.D. Thesis.

Martha Lile Love Award Committee 1992.

Promotion Committee, J.R. Brown 1991.

Search Committee, 1991-2.

Co-ordinator, Logic and Philosophy of Science group 1994 - Member, Mathematical Sciences Review Panel, 1994.

Member, committee for Connaught awards, 1994-7; chair 1995-6

Member, reading committee, P. Apostoli tenure decision, 1996-7.

Jack Zupko
Assistant Professor

Department of Philosophy
Emory University
214 Bowden Hall
Atlanta, GA 30322
(tel. 404 727-0104; 727-6577)

Education

1982 B.A. in Latin and Philosophy (Joint Honours), University of Waterloo
1984-85 Visiting research student in Philosophy, King's College, University of London
1986 M.A. in Philosophy, Cornell University
1989 Ph.D. in Philosophy, Cornell University

Doctoral Dissertation

"John Buridan's Philosophy of Mind: An Edition and Translation of Book III of his `Questions on Aristotle's De anima' (Third Redaction), with Commentary and Critical and Interpretative Essays", under the direction of Norman Kretzmann (UMI #9001313)

Academic Positions Held

1989-93 Assistant Professor of Philosophy at San Diego State University
1993-95 Associate Professor of Philosophy (with tenure) at SDSU
1994-95 Visiting Professor of Franciscan Studies, The Franciscan Institute, St. Bonaventure University
1995- Assistant Professor of Philosophy, Emory University

Areas of Specialization: medieval philosophy; metaphysics and epistemology; philosophy of religion

Areas of Competence: history of philosophy; ethics; logic; philosophy of mind

Selected Publications

Articles

Forthcoming

"John Buridan," in *The Routledge Encyclopedia of Philosophy*, ed. Edward Craig (London: Routledge, to appear in 1998)

"Substance and Soul: The Late Medieval Origins of Early Modern Psychology," in *Meeting of the Minds: The Relations Between Medieval and Classical Modern European Philosophy*, ed. Stephen F. Brown (to appear in 1998)

"Duns Scotus," in the Blackwell *Companion to the Philosophers*, ed. Robert Arrington (Oxford: Basil Blackwell, to appear in 1999)

"Sacred Doctrine; Secular Practice: The Changing Role of Theology in Parisian Natural Philosophy, 1325-1400," in *Miscellanea Mediaevalia 26: What is Philosophy in the Middle Ages? Proceedings of the Tenth International Congress of Medieval Philosophy (SIEPM)* (Berlin: Walter de Gruyter, to appear in 1998)

Review of *Nicolai Oresme: Exposito et Quaestiones in Aristotelis De Anima*, ed. Benoôt Patar (Louvain-Paris: ²ditions Peeters, 1995), in *Early Science and Medicine* (Fall 1998)

In Progress

"Whole Souls and Body Parts: John Buridan's Logic of Inherence" (research article)

"The Metaphysics of Virtue in John Buridan" (research article)

Critical Latin edition of John Buridan's "*Quaestiones in libros Aristotelis `De anima' secundum tertiam (ultimam) lecturam*" (in collaboration with Dr. Peter Sobol, Department of the History of Science, University of Wisconsin)

"John Buridan" (book-length manuscript on Buridan's philosophy)

English translation of Duns Scotus's *Quaestiones in librum Aristotelis Perihermenias* (*opus primum et secundum*); *Quaestiones in libros Aristotelis De sophisticis elenchis*

Selected Presentations

"John Buridan's Theory of Universal Cognition," at the 8th International Congress of Medieval Philosophy (SIEPM), University of Helsinki, 8/28/87

"Buridan's Epistemology," at the Annual Meeting of the Canadian Philosophical Association, Queen's University, Kingston, Ontario, 5/26/91

"William of Ockham, Adam Wodeham, and John Buridan on the Question of Contact Between Continuous Magnitudes," at the Annual Meeting of the Medieval Association of the Pacific, University of California, Irvine CA, 2/21/92

"Freedom of Choice in Buridan's Moral Psychology," at the 9th International Congress of Medieval Philosophy (SIEPM), University of Ottawa, Ottawa, Ontario, 8/19/92

"Intellectual Cognition Explained: The Case of Buridan and Oresme," at the Annual Meeting of the Medieval Academy of America, University of Arizona, Tucson AZ, 4/3/93

"The Metaphysics of Virtue in John Buridan," at a session sponsored by the Society for Medieval and Renaissance Philosophy at the American Philosophical Association Annual Meeting (Eastern Division), Atlanta GA, 12/30/93

"Whole Souls and Body Parts: Buridan's Logic of Inherence," at a colloquium on medieval philosophy at the American Philosophical Association Annual Meeting (Pacific Division), Los Angeles CA, 3/31/94

"What Is the Science of the Soul?: A Case Study in the Evolution of Late Medieval Natural Philosophy," to the Philosophy Department at the University of Toronto, Canada, 1/23/95

"Choosing With Reasons: The Voluntarist/Intellectualist Controversy in Buridan's Philosophy of Action," to the Philosophy Department at Emory University, Atlanta GA, 2/02/95

"The Methodology of Representation: Abelard's Parisian Legacy," at an interdisciplinary conference, `Representation and Interpretation in the 12th Century,' Canisius College, Buffalo NY, 4/21/95

"Augustinianism in Buridan's Theory of the Will," at the 30th International Congress of Medieval Studies, Western Michigan University, 5/06/95

"Substance and Soul in Late Medieval Natural Philosophy," at a conference, "Meeting of the Minds: The Relations between Medieval and Classical Modern European Philosophy," co-sponsored by The Boston College Institute for Medieval Philosophy and Theology and the *Societe Internationale pour l'etude de la Philosophie Medievale* (SIEPM), Boston College, Boston, MA, 6/15/96

"On What Is Truly Trivial," to the Emory University Medieval Studies Roundtable Discussion Group, 3/18/97

"Sacred Doctrine; Secular Practice: The Changing Role of Theology in Parisian Natural Philosophy, 1325-1400," at the 10th International Congress of Medieval Philosophy (SIEPM), Erfurt, Germany, 8/25/97

Grants, Awards, and Academic Distinctions

1989	Research Grant, College of Arts and Letters,

- University of Notre Dame (promotion to full professor), 1991
- University of Michigan-Dearborn (promotion to professor), 1999

- Purdue University (promotion to professor), 1999
- Purdue University (promotion to Distinguished professor), 1999

Chair of the Committee on Committees of the Board of Officers of the American Philosophical Association for their general meeting in Philadelphia, October 3-5, 1991.

Chair of the Alfred Schutz Lectureship Committee of the American Philosophical Association (summer, 1991).

Co-Chair, Program Committee for the 1989 meeting of the International Association for Philosophy and Literature, Atlanta, GA, May 4-6, 1989.

Member of the Board of Officers of the American Philosophical Association (Representative of the Eastern Division), 1989-92.

Member Executive Committee of the American Catholic Philosophical Association, 1988-91.

Member Executive Committee of the International Association for Philosophy and Literature, 1988-93.

Chair, Executive Board of the Sartre Society of North America, 1988-91.

Chair, Program Committee for the 1987 meeting of the American Philosophical Association, Eastern Division. Responsible for the program of the largest annual meeting of philosophers in North America.

Program Committee for the 1986 meeting of the American Philosophical Association, Eastern Division (assess numerous submissions).

Program Committee for the 1986 meeting of the Society for Phenomenology and Existential Philosophy (assess scores of submissions).

Board of Directors of the Society for Phenomenology & Existential Philosophy, 1983-86.

Review Editor for Man and World, an international journal of philosophy, 1978-1997.

Referee for National Endowment for the Humanities (Special Programs) July 1986 and May 1992, and on a review panel, March 5 & 6, 1987; again (Research Programs) June, 1987.

Referee for University Presses: Chicago, Indiana, SUNY, Mercer, Penn State.

Founding member of Committee to establish an international Sartre Society. Inaugural conference, October 4-6, 1985, The New School, New York City.

Referee of submitted papers for the conference. Introduce keynote speaker. Referee of submitted papers for the 1987 and 1988 conferences.

Program Chairman of 1981 national meeting of the Metaphysical Society of America.

Member of:

- The American Philosophical Association.
- The Society for Phenomenology and Existential Philosophy.
- The Metaphysical Society.
- The American Catholic Philosophical Association.

National Treasurer of The American Catholic Philosophical Association and Business Manager of its review, The New Scholasticism, 1971-75.

International Association for Philosophy and Literature.

Assistant to the Dean, School of Philosophy, Catholic University, coordinating the programs of all undergraduate majors in philosophy, 1971-74.

Exchange graduate professor of philosophy, American University, Washington, DC, Fall term, 1973.

Member of curriculum committees both of the College of Arts and Sciences and of the School of Philosophy, Catholic University, 1971-75.

Chairman of the Curriculum Committee, School of Philosophy, Catholic University of America, 1973-74.

Service to the University

Chairman, Committee to Plan a Core Course for Freshmen, 1981-82.

Faculty Senate, Emory University, 1982-84.

University Research Committee, 1982-83.

Member of Committee on General Education, reviewing the general distribution requirements of Emory College, 1984-86.

Academic advisor to Merit Scholars, Emory College, 1980-83.

Member of the President's Committee on Undergraduate Education, Emory University.

Member, Admissions & Scholarship Committee, Emory College, 1979-83.

Chairman, Subcommittee of the President's Committee on Undergraduate Education, dealing with the Freshman Experience, 1980-81.

Chaplain's Advisory Committee on Religious Policy, 1979- .

Committee on the Emory College Advisory Program, 1980-81.

Lilly Endowment Summer Research Seminar, June, 1981.

Dobbs Hall Experiment in advising, 1981-83.

Chair of Emory Williams Teaching Award Committee 1984-85.

Academic advisor to Honors Students, Emory College, 1985- .

President's Advisory Committee on South Africa, 1985-86.

Consultant on Ford Foundation Proposal, 1985-86.

Consultant on Proposal for a Henry Luce Professorship at Emory, 1985-86.

Member of Search Committee for a Henry Luce Professor, 1986-87.

Member of Educational Policy Committee, Acting Chair, Fall 1985.

Member of Scholar/Teacher of the Year nominating committee, 1987, 1988, and 1990.

Member of the Business School Ethics Task Force, 1988-89.

Member of Search Committee for University Chaplain, 1989-90.

Member of College Committee to evaluate the fraternity/sorority system on campus (1990-91).

Member of Dean's Committee to review leave and release time policy in the College (1992).

Chair, Department of Philosophy (1988-91).

Chair, Center for Language, Literature, and Culture, Emory Univ., 1992-94.

Fulbright Interview Committee, 1992- .

Advisory Committee, Culture, History, Theory Program (ILA), 1993- .

Steering Committee, Friends of Theater Emory, 1993-95.

Member, Cannon Chapel Committee, 1993-94.

Member, University Committee on Law and Religion, 1995- .

Member, Advisory Committee on Center for Curricular Renewal and Teaching Enhancement, Emory College, 1995- .

Member, ad hoc Advisory Committee to Provost on disputed tenure decision, Dec.-Jan. 1996-97.

Associated Faculty of the Aquinas Center, Emory, 1997- .

Addendum

Radio interview with Wayne Pond for "Soundings" on PBS. Topic, "The Public Philosophy." Aired over two hundred PBS stations in March, 1992.

Television interview with Canadian television company for a 2-hour program on"Life After Death," aired on Canadian television last Spring and in the United States, on the Learning Channel, December, 1997.

Evolutionary Game Theory

Evolutionary game theory originated as an application of the mathematical theory of games to biological contexts, arising from the realization that frequency dependent fitness introduces a strategic aspect to evolution. Recently, however, evolutionary game theory has become of increased interest to economists, sociologists, and anthropologists--and social scientists in general--as well as philosophers. The interest among social scientists in a theory with explicit biological roots derives from three facts. First, the ‘evolution’ treated by evolutionary game theory need not be biological evolution. ‘Evolution’ may, in this context, often be understood as *cultural* evolution, where this refers to changes in beliefs and norms over time. Second, the rationality assumptions underlying evolutionary game theory are, in many cases, more appropriate for the modelling of social systems than those assumptions underlying the traditional theory of games. Third, evolutionary game theory, as an explicitly dynamic theory, provides an important element missing from the traditional theory. In the preface to *Evolution and the Theory of Games*, Maynard Smith notes that "[p]aradoxically, it has turned out that game theory is more readily applied to biology than to the field of economic behaviour for which it was originally designed." It is perhaps doubly paradoxical, then, that the subsequent development of *evolutionary* game theory has produced a theory which holds great promise for social scientists, and is as readily applied to the field of economic behaviour as that for which it was originally designed.

1. Historical Development

Evolutionary game theory was first developed by R. A. Fisher [see *The Genetic Theory of Natural Selection* (1930)] in his attempt to explain the approximate equality of the sex ratio in mammals. The puzzle Fisher faced

was this: why is it that the sex ratio is approximately equal in many species where the majority of males never mate? In these species, the non-mating males would seem to be excess baggage carried around by the rest of the population, having no real use. Fisher realized that if we measure individual fitness in terms of the expected number of *grandchildren*, then individual fitness depends on the distribution of males and females in the population. When there is a greater number of females in the population, males have a higher individual fitness; when there are more males in the population, females have a higher individual fitness. Fisher pointed out that, in such a situation, the evolutionary dynamics lead to the sex ratio becoming fixed at equal numbers of males and females. The fact that individual fitness depends upon the relative frequency of males and females in the population introduces a strategic element into evolutions.

Fisher's argument can be understood game theoretically, but he did not state it in those terms. In 1961, R. C. Lewontin made the first explicit application of game theory to evolutionary biology in "Evolution and the Theory of Games" (not to be confused with the Maynard Smith work of the same name). In 1972, Maynard Smith defined the concept of an *evolutionarily stable strategy* (hereafter ESS) in the article "Game Theory and the Evolution of Fighting." However, it was the publication of "The Logic of Animal Conflict," by Maynard Smith and Price in 1973 that introduced the concept of an ESS into widespread circulation. In 1982, Maynard Smith's seminal text *Evolution and the Theory of Games* appeared, followed shortly thereafter by Robert Axelrod's famous work *The Evolution of Cooperation* in 1984. Since then, there has been a veritable explosion of interest by economists and social scientists in evolutionary game theory (see the bibliography below).

2. Two Approaches to Evolutionary Game Theory

There are two approaches to evolutionary game theory. The first approach derives from the work of Maynard Smith and Price and employs the concept of an evolutionarily stable strategy as the principal tool of analysis. The second approach constructs an explicit model of the process by which the frequency of strategies change in the population and studies properties of the evolutionary dynamics within that model.

As an example of the first approach, consider the problem of the Hawk-Dove game, analyzed by Maynard Smith and Price in "The Logic of Animal Conflict." In this game, two individuals compete for a resource of a fixed value *V*. (In biological contexts, the value *V* of the resource corresponds to an increase in the Darwinian fitness of the individual who obtains the resource; in a cultural context, the value *V* of the resource would need to be given an alternate interpretation more appropriate to the specific model at hand.) Each individual follows exactly one of two strategies described below:

Hawk	Initiate aggressive behaviour, not stopping until injured or until one's opponent backs down.
Dove	Retreat immediately if one's opponent initiates aggressive behaviour.

If we assume that (1) whenever two individuals both initiate aggressive behaviour, conflict eventually results and the two individuals are equally likely to be injured, (2) the cost of the conflict reduces individual fitness by some constant value *C*, (3) when a Hawk meets a Dove, the Dove immediately retreats and the Hawk obtains the resource, and (4) when two Doves meet the resource is shared equally between them, the fitness payoffs for the Hawk-Dove game can be summarized according to the following matrix:

	Hawk	**Dove**

Hawk	½(V - C)	V
Dove	0	V/2

Figure 1: The Hawk-Dove Game

(The payoffs listed in the matrix are for that of a player *using* the strategy in the appropriate row, playing against someone using the strategy in the appropriate column. For example, if you play the strategy Hawk against an opponent who plays the strategy Dove, your payoff is V; if you play the strategy Dove against an opponent who plays the strategy Hawk, your payoff is 0.)

In order for a strategy to be evolutionarily stable, it must have the property that if almost every member of the population follows it, no mutant (that is, an individual who adopts a novel strategy) can successfully invade. This idea can be given a precise characterization as follows: Let $\Delta F(s_1,s_2)$ denote the change in fitness for an individual following strategy s_1 against an opponent following strategy s_2, and let $F(s)$ denote the total fitness of an individual following strategy s; furthermore, suppose that each individual in the population has an initial fitness of F_0. If σ is an evolutionarily stable strategy and μ a mutant attempting to invade the population, then

$$F(\sigma) = F_0 + (1-p)\Delta F(\sigma,\sigma) + p\Delta F(\sigma,\mu)$$

$$F(\mu) = F_0 + (1-p)\Delta F(\mu,\sigma) + p\Delta F(\mu,\mu)$$

where p is the proportion of the population following the mutant strategy μ.

Since σ is evolutionarily stable, the fitness of an individual following σ must be greater than the fitness of an individual following μ (otherwise the mutant following μ would be able to invade), and so $F(\sigma) > F(\mu)$. Now, as p is very close to 0, this requires that *either* that

$$\Delta F(\sigma,\sigma) > \Delta F(\sigma,\mu)$$

or that

$$\Delta F(\sigma,\sigma) = \Delta F(\sigma,\mu) \text{ and } \Delta F(\sigma,\mu) > \Delta F(\mu,\mu)$$

(This is the definition of an ESS that Maynard Smith and Price give.) In other words, what this means is that a strategy σ is an ESS if one of two conditions holds: (1) σ does better playing against σ than any mutant does playing against σ, or (2) some mutant does just as well playing against σ as σ, but σ does better playing against the mutant than the mutant does.

Given this characterization of an evolutionarily stable strategy, one can readily confirm that, for the Hawk-Dove game, the strategy Dove is not evolutionarily stable because a pure population of Doves can be invaded by a Hawk mutant. If the value V of the resource is greater than the cost C of injury (so that it is worth risking injury in order to obtain the resource), then the strategy Hawk is evolutionarily stable. In the case where the value of the resource is *less* than the cost of injury, there is no evolutionarily stable strategy if individuals are restricted to following pure strategies, although there is an evolutionarily stable strategy if players may use mixed strategies.[1]

As an example of the second approach, consider the well-known Prisoner's Dilemma. In this game, individuals choose one of two strategies, typically called "Cooperate" and "Defect." Here is the general form of the payoff matrix for the prisoner's dilemma:

	Cooperate	**Defect**
Cooperate	(R,R')	(S,T')
Defect	(T,S')	(P,P')

Figure 2: Payoff Matrix for the Prisoner's Dilemma.
Payoffs listed as (row, column).

where $T > R > P > S$ and $T' > R' > P' > S'$. (This form does not require that the payoffs for each player be symmetric, only that the proper ordering of the payoffs obtains.) In what follows, it will be assumed that the payoffs for the Prisoner's Dilemma are the same for everyone in the population.

How will a population of individuals that repeatedly plays the Prisoner's Dilemma evolve? We cannot answer that question without introducing a few assumptions concerning the nature of the population. First, let us assume that the population is quite large. In this case, we can represent the state of the population by simply keeping track of what proportion follow the strategies Cooperate and Defect. Let p_c and p_d denote these proportions. Furthermore, let us denote the average fitness of cooperators and defectors by W_C and W_D, respectively, and let $\overline{W}$ denote the average fitness of the entire population. The values of W_C, W_D, and $\overline{W}$ can be expressed in terms of the population proportions and payoff values as follows:

$$W_D = F_0 + p_c \triangle F(C,C) + p_d \triangle F(C,D)$$
$$W_D = F_0 + p_c \triangle F(D,C) + p_d \triangle F(D,D)$$
$$\overline{W} = p_c W_C + p_d W_D$$

Second, let us assume that the proportion of the population following the strategies Cooperate and Defect in the next generation is related to the proportion of the population following the strategies Cooperate and Defect in the current generation according to the rule:

$$p_c' = \frac{p_c W_C}{\overline{W}} \qquad p_d' = \frac{p_d W_D}{\overline{W}}$$

We can rewrite these expressions in the following form:

$$p_c' - p_c = \frac{p_c(W_C - \overline{W})}{\overline{W}} \qquad p_d' - p_d = \frac{p_d(W_D - \overline{W})}{\overline{W}}$$

If we assume that the change in the strategy frequency from one generation to the next are small, these difference

equations may be approximated by the differential equations:

$$\frac{dp_c}{dt} = \frac{p_c(W_C - \overline{W})}{\overline{W}} \qquad \frac{dp_d}{dt} = \frac{p_d(W_D - \overline{W})}{\overline{W}}$$

These equations were offered by Taylor and Jonker (1978) and Zeeman (1979) to provide continuous dynamics for evolutionary game theory and are known as the *replicator dynamics*.

The replicator dynamics may be used to model a population of individuals playing the Prisoner's Dilemma. For the Prisoner's Dilemma, the expected fitness of Cooperating and Defecting are:

$$\begin{aligned} W_C &= F_0 + p_c \triangle F(C,C) + p_d \triangle F(C,D) \\ &= F_0 + p_c R + p_d S \end{aligned}$$

and

$$\begin{aligned} W_D &= F_0 + p_c \triangle F(D,C) + p_d \triangle F(D,D) \\ &= F_0 + p_c T + p_d P. \end{aligned}$$

Since $T > R$ and $P > S$, it follows that $W_D > W_C$ and hence $W_D > \overline{W} > W_C$. This means that

$$\frac{W_D - \overline{W}}{\overline{W}} > 0$$

and

$$\frac{W_C - \overline{W}}{\overline{W}} < 0$$

Since the strategy frequencies for Defect and Cooperate in the next generation are given by

$$p'_d = p_d \cdot \frac{W_D - \overline{W}}{\overline{W}}$$

and

$$p'_c = p_c \cdot \frac{W_C - \overline{W}}{\overline{W}}$$

respectively, we see that over time the proportion of the population choosing the strategy Cooperate eventually becomes extinct. Figure 3 illustrates one way of representing the replicator dynamical model of the prisoner's

dilemma, known as a state-space diagram.

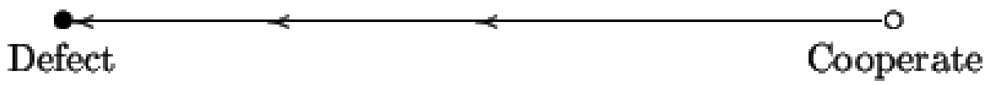

Figure 3: The Replicator Dynamical Model of the Prisoner's Dilemma

We interpret this diagram as follows: the leftmost point represents the state of the population where everyone defects, the rightmost point represents the state where everyone cooperates, and intermediate points represent states where some proportion of the population defects and the remainder cooperates. (One maps states of the population onto points in the diagram by mapping the state when *N*% of the population defects onto the point of the line *N*% of the way to the leftmost point.) Arrows on the line represent the evolutionary trajectory followed by the population over time. The open circle at the rightmost point indicates that the state where everybody cooperates is an unstable equilibrium, in the sense that if a small portion of the population deviates from the strategy Cooperate, then the evolutionary dynamics will drive the population away from that equilibrium. The solid circle at the leftmost point indicates that the state where everybody Defects is a stable equilibrium, in the sense that if a small portion of the population deviates from the strategy Defect, then the evolutionary dynamics will drive the population back to the original equilibrium state.

At this point, one may see little difference between the two approaches to evolutionary game theory. One can confirm that, for the Prisoner's Dilemma, the state where everybody defects is the only ESS. Since this state is the only stable equilibrium under the replicator dynamics, the two notions fit together quite neatly: the only stable equilibrium under the replicator dynamics occurs when everyone in the population follows the only ESS. In general, though, the relationship between ESSs and stable states of the replicator dynamics is more complex than this example suggests. Taylor and Jonker (1978), as well as Zeeman (1979), establish conditions under which one may infer the existence of a stable state under the replicator dynamics given an evolutionarily stable strategy. Roughly, if only two pure strategies exist, then given a (possibly mixed) evolutionarily stable strategy, the corresponding state of the population is a stable state under the replicator dynamics. (If the evolutionarily stable strategy is a mixed strategy *S*, the corresponding state of the population is the state in which the proportion of the population following the first strategy equals the probability assigned to the first strategy by *S*, and the remainder follow the second strategy.) However, this can fail to be true if more than two pure strategies exist.

The connection between ESSs and stable states under an evolutionary dynamical model is weakened further if we do not model the dynamics by the replicator dynamics. For example, suppose we use a local interaction model in which each individual plays the prisoner's dilemma with his or her neighbors. Nowak and May (1992, 1993), using a spatial model in which local interactions occur between individuals occupying neighboring nodes on a square lattice, show that stable population states for the prisoner's dilemma depend upon the specific form of the payoff matrix.[2]

When the payoff matrix for the population has the values $T = 2.8$, $R = 1.1$, $P = 0.1$, and $S = 0$, the evolutionary dynamics of the local interaction model agree with those of the replicator dynamics, and lead to a state where each individual follows the strategy Defect--which is, as noted before, the only evolutionarily stable strategy in the prisoner's dilemma. The figure below illustrates how rapidly one such population converges to a state where everyone defects.

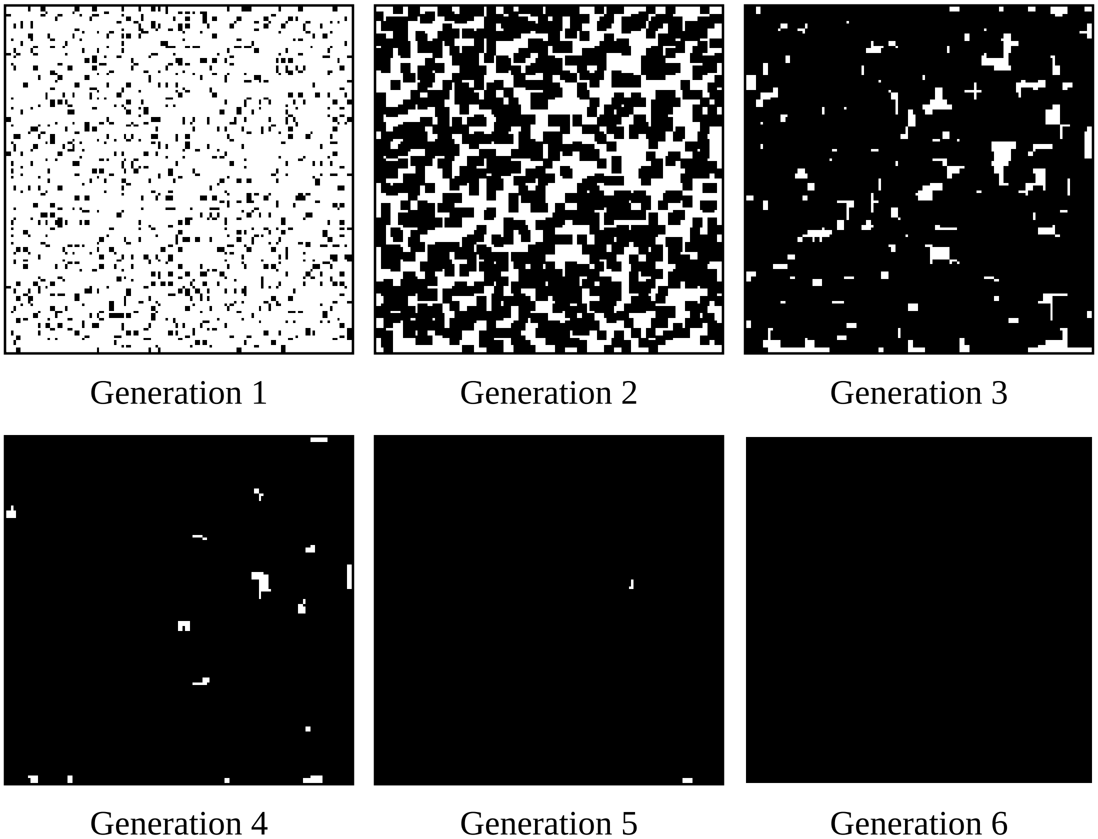

Figure 4: Prisoner's Dilemma: All Defect
[view a movie of this model]

However, when the payoff matrix has values of T = 1.2, R = 1.1, P = 0.1, and S = 0, the evolutionary dynamics carry the population to a stable cycle oscillating between two states. In this cycle cooperators and defectors coexist, with some regions containing "blinkers" oscillating between defectors and cooperators (as seen in generation 19 and 20).

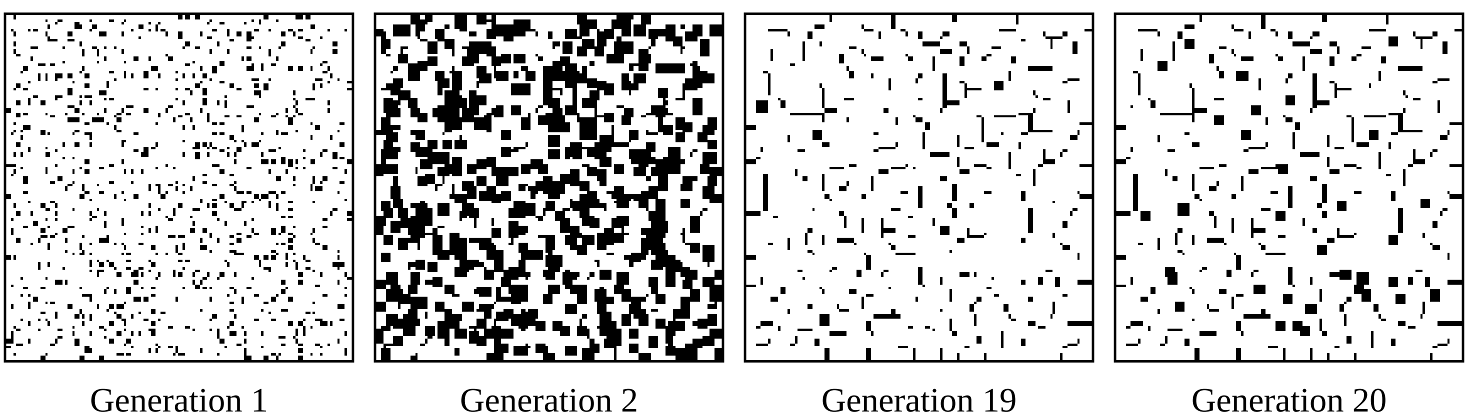

Figure 5: Prisoner's Dilemma: Cooperate
[view a movie of this model]

Notice that with these particular settings of payoff values, the evolutionary dynamics of the local interaction model differ significantly from those of the replicator dynamics. Under these payoffs, the stable states have no

corresponding analogue in either the replicator dynamics nor in the analysis of evolutionarily stable strategies.

A phenomenon of greater interest occurs when we choose payoff values of $T = 1.61$, $R = 1.01$, $P = 0.01$, and $S = 0$. Here, the dynamics of local interaction lead to a world constantly in flux: under these values regions occupied predominantly by Cooperators may be successfully invaded by Defectors, and regions occupied predominantly by Defectors may be successfully invaded by Cooperators. In this model, there is no "stable strategy" in the traditional dynamical sense.[3]

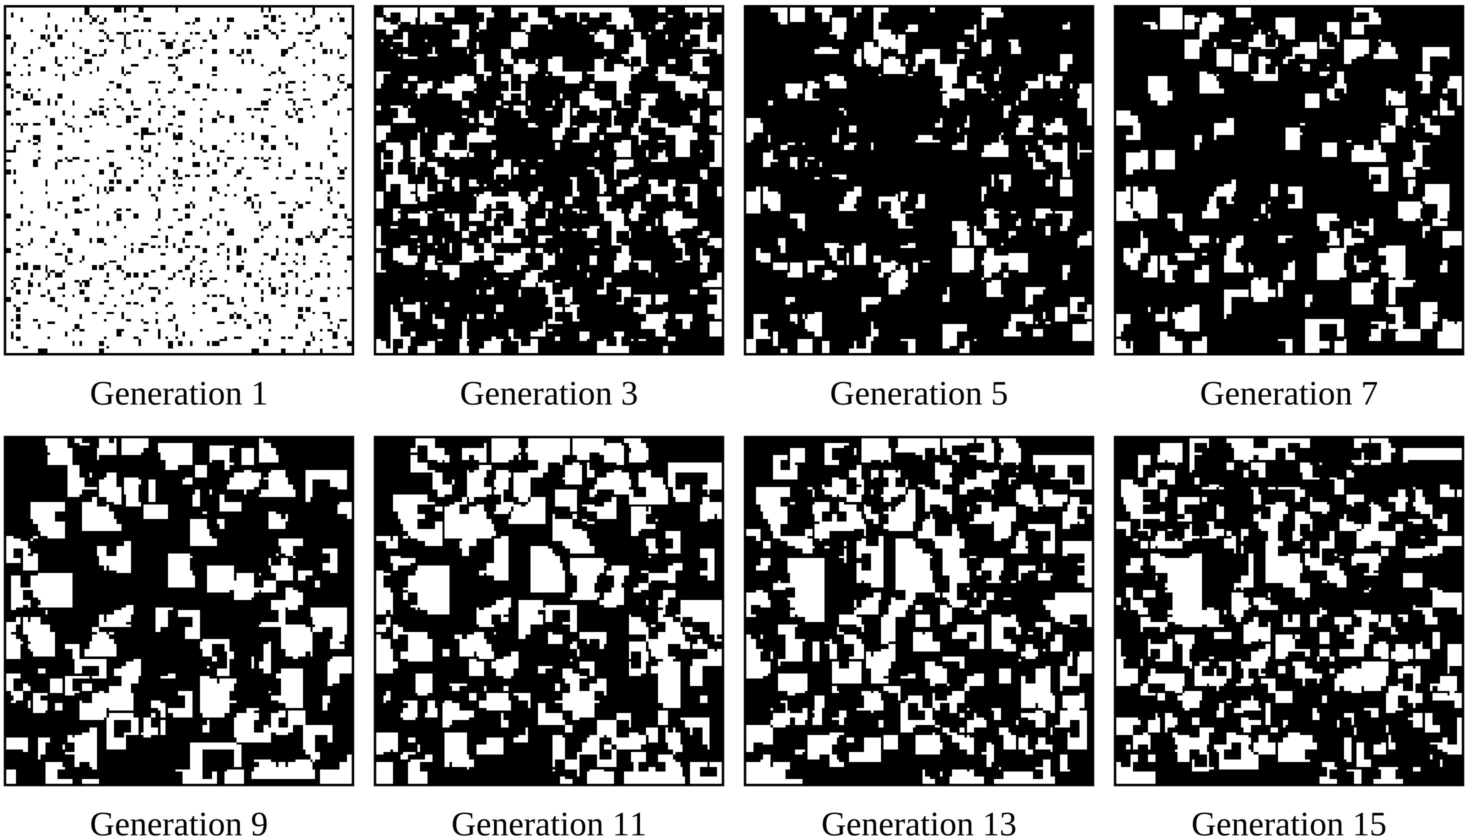

Figure 6: Prisoner's Dilemma: Chaotic
[view a movie of this model]

These models demonstrate that, although numerous cases exist in which both approaches to evolutionary game theory arrive at the same conclusion regarding which strategies one would expect to find present in a population, there are enough differences in the outcomes of the two modes of analysis to justify the development of each program.

3. Why Evolutionary Game Theory?

Although evolutionary game theory has provided numerous insights to particular evolutionary questions, a growing number of social scientists have become interested in evolutionary game theory in hopes that it will provide tools for addressing a number of deficiencies in the traditional theory of games, three of which are discussed below.

3.1 The equilibrium selection problem

The concept of a Nash equilibrium (see the entry on game theory) has been the most used solution concept in game theory since its introduction by John Nash in 1950. A selection of strategies by a group of agents is said to be in a Nash equilibrium if each agent's strategy is a best-response to the strategies chosen by the other players. By best-response, we mean that no individual can improve her payoff by switching strategies unless at least one other individual switches strategies as well. This need not mean that the payoffs to each individual are optimal in a Nash equilibrium: indeed, one of the disturbing facts of the prisoner's dilemma is that the only Nash equilbrium of the game--when both agents defect--is suboptimal.[4]

Yet a difficulty arises with the use of Nash equilibrium as a solution concept for games: if we restrict players to using pure strategies, not every game has a Nash equilbrium. The game "Matching Pennies" illustrates this problem.

	Heads	**Tails**
Heads	(0,1)	(1,0)
Tails	(1,0)	(0,1)

Figure 7: Payoff matrix for the game of Matching Pennies
(Row wins if the two coins do not match, whereas Column wins if the two coins match).

While it is true that every noncooperative game in which players may use mixed strategies has a Nash equilibrium, some have questioned the significance of this for real agents. If it seems appropriate to require rational agents to adopt only pure strategies (perhaps because the cost of implementing a mixed strategy runs too high), then the game theorist must admit that certain games lack solutions.

A more significant problem with invoking the Nash equilibrium as the appropriate solution concept arises because games exist which have multiple Nash equilibria (see Section 2.5, Solution Concepts and Equilibria, in the entry on game theory). When there are several different Nash equilibria, how is a rational agent to decide which of the several equilibria is the "right one" to settle upon?[5] Attempts to resolve this problem have produced a number of possible refinements to the concept of a Nash equilibrium, each refinement having some intuitive purchase. Unfortunately, so many refinements of the notion of a Nash equilibrium have been developed that, in many games which have multiple Nash equilibria, each equilibrium could be justified by some refinement present in the literature. The problem has thus shifted from choosing among multiple Nash equilibria to choosing among the various refinements. Some (see Samuelson (1997), *Evolutionary Games and Equilibrium Selection*) hope that further development of evolutionary game theory can be of service in addressing this issue.

3.2 The problem of hyperrational agents

The traditional theory of games imposes a very high rationality requirement upon agents. This requirement originates in the development of the theory of utility which provides game theory's underpinnings (see Luce (1950) for an introduction). For example, in order to be able to assign a cardinal utility function to individual agents, one typically assumes that each agent has a well-defined, consistent set of preferences over the set of "lotteries" over the outcomes which may result from individual choice. Since the number of different lotteries over outcomes is uncountably infinite, this requires each agent to have a well-defined, consistent set of uncountably infinitely many

preferences.

Numerous results from experimental economics have shown that these strong rationality assumptions do not describe the behavior of real human subjects. Humans are rarely (if ever) the hyperrational agents described by traditional game theory. For example, it is not uncommon for people, in experimental situations, to indicate that they prefer *A* to *B*, *B* to *C*, and *C* to *A*. These "failures of the transitivity of preference" would not occur if people had a well-defined consistent set of preferences. Furthermore, experiments with a class of games known as a "beauty pageant" show, quite dramatically, the failure of common knowledge assumptions typically invoked to solve games.[6] Since evolutionary game theory successfully explains the predominance of certain behaviors of insects and animals, where strong rationality assumptions clearly fail, this suggests that rationality is not as central to game theoretic analyses as previously thought. The hope, then, is that evolutionary game theory may meet with greater success in describing and predicting the choices of human subjects, since it is better equipped to handle the appropriate weaker rationality assumptions.

3.3 The lack of a dynamical theory in the traditional theory of games

At the end of the first chapter of *Theory of Games and Economic Behavior,* von Neumann and Morgenstern write:

> We repeat most emphatically that our theory is thoroughly static. A dynamic theory would unquestionably be more complete and therefore preferable. But there is ample evidence from other branches of science that it is futile to try to build one as long as the static side is not thoroughly understood. (Von Neumann and Morgenstern, 1953, p. 44)

The theory of evolution is a dynamical theory, and the second approach to evolutionary game theory sketched above explicitly models the dynamics present in interactions among individuals in the population. Since the traditional theory of games lacks an explicit treatment of the dynamics of rational deliberation, evolutionary game theory can be seen, in part, as filling an important lacuna of traditional game theory.

One may seek to capture some of the dynamics of the decision-making process in traditional game theory by modeling the game in its extensive form, rather than its normal form. However, for most games of reasonable complexity (and hence interest), the extensive form of the game quickly becomes unmanageable. Moreover, even in the extensive form of a game, traditional game theory represents an individual's strategy as a specification of what choice that individual would make at each information set in the game. A selection of strategy, then, corresponds to a selection, prior to game play, of what that individual will do at any possible stage of the game. This representation of strategy selection clearly presupposes hyperrational players and fails to represent the process by which one player observes his opponent's behavior, learns from these observations, and makes the best move in response to what he has learned (as one might expect, for there is no need to model learning in hyperrational individuals). The inability to model the dynamical element of game play in traditional game theory, and the extent to which evolutionary game theory naturally incorporates dynamical considerations, reveals an important virtue of evolutionary game theory.

4. Philosophical Problems of Evolutionary Game Theory

The growing interest among social scientists and philosophers in evolutionary game theory has raised several philosophical questions, primarily stemming from its application to human subjects.

4.1 The meaning of fitness in cultural evolutionary interpretations

As noted previously, evolutionary game theoretic models may often be given both a biological and a cultural evolutionary interpretation. In the biological interpretation, the numeric quantities which play a role analogous to "utility" in traditional game theory correspond to the fitness (typically Darwinian fitness) of individuals.[7] How does one interpret "fitness" in the cultural evolutionary interpretation?

In many cases, fitness in cultural evolutionary interpretations of evolutionary game theoretic models directly measures some objective quantity of which it can be safely assumed that (1) individuals always want more rather than less and (2) interpersonal comparisons are meaningful. Depending on the particular problem modeled, money, slices of cake, or amount of land would be appropriate cultural evolutionary interpretations of fitness. Requiring that fitness in cultural evolutionary game theoretic models conform to this interpretative constraint severely limits the kinds of problems that one can address. A more useful cultural evolutionary framework would provide a more general theory which did not require that individual fitness be a linear (or strictly increasing) function of the amount of some real quantity, like amount of food.

In traditional game theory, a strategy's fitness was measured by the expected utility it had for the individual in question. Yet evolutionary game theory seeks to describe individuals of limited rationality (commonly known as "boundedly rational" individuals), and the utility theory employed in traditional game theory assumes highly rational individuals. Consequently, the utility theory used in traditional game theory cannot simply be carried over to evolutionary game theory. One must develop an alternate theory of utility/fitness, one compatible with the bounded rationality of individuals, that is sufficient to define a utility measure adequate for the application of evolutionary game theory to cultural evolution.

4.2 The explanatory irrelevance of evolutionary game theory

Another question facing evolutionary game theoretic explanations of social phenomena concerns the kind of explanation it seeks to give. Depending on the type of explanation it seeks to provide, are evolutionary game theoretic explanations of social phenomena irrelevant or mere vehicles for the promulgation of pre-existing values and biases? To understand this question, recognize that one must ask whether evolutionary game theoretic explanations target the etiology of the phenomenon in question, the persistence of the phenomenon, or various aspects of the normativity attached to the phenomenon. The latter two questions seem deeply connected, for population members typically enforce social behaviors and rules having normative force by sanctions placed on those failing to comply with the relevant norm; and the presence of sanctions, if suitably strong, explains the persistence of the norm. The question regarding a phenomenon's etiology, on the other hand, can be considered independent of the latter questions.

If one wishes to explain how some currently existing social phenomenon came to be, it is unclear why approaching it from the point of view of evolutionary game theory would be particularily illuminating. The etiology of any phenomenon is a unique historical event and, as such, can only be discovered empirically, relying on the work of sociologists, anthropologists, archaeologists, and the like. Although an evolutionary game theoretic model may exclude certain historical sequences as possible histories (since one may be able to show that the cultural evolutionary dynamics preclude one sequence from generating the phenomenon in question), it seems unlikely that an evolutionary game theoretic model would indicate a unique historical sequence suffices to bring about the phenomenon. An empirical inquiry would then still need to be conducted to rule out the extraneous historical

sequences admitted by the model, which raises the question of what, if anything, was gained by the construction of an evolutionary game theoretic model in the intermediate stage. Moreover, even if an evolutionary game theoretic model indicated that a single historical sequence was capable of producing a given social phenomenon, there remains the important question of why we ought to take this result seriously. One may point out that since nearly any result can be produced by a model by suitable adjusting of the dynamics and initial conditions, all that the evolutionary game theorist has done is provide one such model. Additional work needs to be done to show that the underlying assumptions of the model (both the cultural evolutionary dynamics and the initial conditions) are empirically supported. Again, one may wonder what has been gained by the evolutionary model--would it not have been just as easy to determine the cultural dynamics and initial conditions beforehand, constructing the model afterwards? If so, it would seem that the contributions made by evolutionary game theory in this context simply are a proper part of the parent social science--sociology, anthropology, economics, and so on. If so, then there is nothing *particular* about evolutionary game theory employed in the explanation, and this means that, contrary to appearances, evolutionary game theory is really irrelevant to the given explanation.

If evolutionary game theoretic models do not explain the etiology of a social phenomenon, presumably they explain the persistence of the phenomenon or the normativity attached to it. Yet we rarely need an evolutionary game theoretic model to identify a particular social phenomenon as stable or persistent as that can be done by observation of present conditions and examination of the historical records; hence the charge of irrelevancy is raised again. Moreover, most of the evolutionary game theoretic models developed to date have provided the crudest approximations of the real cultural dynamics driving the social phenomenon in question. One may well wonder why, in these cases, we should take seriously the stability analysis given by the model; answering this question would require one engage in an empirical study as previously discussed, ultimately leading to the charge of irrelevance again.

4.3 The value-ladenness of evolutionary game theoretic explanations

If one seeks to use an evolutionary game theoretic model to explain the normativity attached to a social rule, one must explain how such an approach avoids committing the so-called "naturalistic fallacy" of inferring an ought-statement from a conjunction of is-statements.[8] Assuming that the explanation does not commit such a fallacy, one argument charges that it must then be the case that the evolutionary game theoretic explanation merely repackages certain key value claims tacitly assumed in the construction of the model. After all, since any argument whose conclusion is a normative statement must have at least one normative statement in the premises, any evolutionary game theoretic argument purporting to show how certain norms acquire normative force must contain--at least implicitly--a normative statement in the premises. Consequently, this application of evolutionary game theory does not provide a neutral analysis of the norm in question, but merely acts as a vehicle for advancing particular values, namely those smuggled in the premises.

This criticism seems less serious than the charge of irrelevancy. Cultural evolutionary game theoretic explanations of norms need not "smuggle in" normative claims in order to draw normative conclusions. The theory already contains, in its core, a proper subtheory having normative content--namely a theory of rational choice in which boundedly rational agents act in order to maximize, as best as they can, their own self-interest. One may challenge the suitability of this as a foundation for the normative content of certain claims, but this is a different criticism from the above charge. Although cultural evolutionary game theoretic models do act as vehicles for promulgating certain values, they wear those minimal value commitments on their sleeve. Evolutionary explanations of social norms have the virtue of making their value commitments explicit and also of showing how other normative commitments (such as fair division in certain bargaining situations, or cooperation in the prisoner's dilemma) may

be derived from the principled action of boundedly rational, self-interested agents.

Bibliography

Stanford Encyclopedia of Philosophy
Occasional Referees

The following philosophers have served as referees on those occasions when their expertise on a topic made them particularly appropriate.

- David Barker-Plummer (Stanford University)
- Jeffrey Blustein (Albert Einstein College of Medicine)
- Stuart Brock (Western Washington University)
- Johan van Benthem (University of Amsterdam and Stanford University)
- Earl Conee (University of Rochester)
- Max Cresswell (Victoria University of Wellington)
- John Divers (University of Leeds)
- Greg Fitch (Arizona State University)
- Branden Fitelson (Stanford University)
- Lou Goble (Willamette University)
- Ruth Grant (Duke University)
- Lori Gruen (Wesleyan University)
- Bob Hale (University of Glasgow)
- Thomas Hofweber (University of Michigan)
- David Israel (SRI/Menlo Park)
- Ernie Lepore (Rutgers University)
- Bernard Linsky (University of Alberta)
- Kirk Ludwig (University of Florida)
- Paul McNamara (University of New Hampshire)
- Christopher Menzel (Texas A&M University)
- Karl-Georg Niebergall (Universität München)
- Francis Jeffry Pelletier (University of Alberta)
- William Throop (Green Mountain College)
- Peter Vanderschraaf (Carnegie-Mellon University)
- Gary Varner (Texas A&M University)
- Albert Visser (University of Utrecht)

Entry Content: Guidelines and Policies

In this document, we develop guidelines and policies concerning the content of entries written for the *Stanford Encyclopedia of Philosophy*.

Entry Substance, Style, and Length

The *Stanford Encyclopedia of Philosophy* is intended to serve as an authoritative reference work suitable for use by professionals and students in the field of philosophy, as well as by all others interested in authoritative discussions on philosophical topics. Entries should therefore be written with the highest of professional standards, and be of interest to as wide an audience as possible. Entries should focus on the philosophical issues and arguments rather than on sociology and individuals, particularly in discussions of topics in contemporary philosophy. In other words, entries should be "idea-driven" and not "people-driven". Bibliographic entries should be critical and not hagiographical. Authors should strive to *minimize the use of jargon*.

All entries should provide objective, neutral analyses or surveys of particular topics, rather than promoting idiosyncratic or controversial points of view. Authors should see their task as one of offering a broad or insightful perspective which introduces both the topic and the literature and which puts the reader into position to read the primary and secondary sources cited in the entry. (To this end, the sources of all quotations should be clearly identified.) Clarity of substance and style should also be one of the most important goals.

Encyclopedia entries should therefore not be polemical. Controversial claims should be identified as such. Authors should not use the first person pronoun "I", and should avoid such constructions as "as I have argued elsewhere/previously...". In addition, authors should not cite or refer to unpublished or inaccessible materials, and in particular, to unpublished dissertations or talks. Authors should also be circumspect in the number of references to their own work, though obviously, since they are experts on the topic and typically will have written widely on it, occasional references will be in order and appropriate. The editors of the *Encyclopedia* will ensure that entries do not overstep the bounds of propriety in this regard.

The length of entries should depend on the topic. Entries will typically range from 7,000-8,000 words, but may be anywhere from half this long to twice this long depending on the how broadly the topic is focused and how much literature there is to introduce and explain. We encourage authors to organize longer entries by writing a set of nested, cross-linked documents rather than by writing a single, linear document. By this we mean that overly detailed, highly technical, or highly scholarly material should be put into separate HTML ("supplementary") documents and linked into the main entry. (See below.) This way, the main entry should become readable by an intelligent undergraduate in a sitting of about an hour or two. More advanced readers can follow the links to the highly technical, detailed or scholarly material. Such a cross-linked set of documents will therefore be accessible to a wide audience. However, authors should create such "nested" entries only if it seems unlikely that a separate entry in the *Encyclopedia* will be created to discuss the supplementary material.

Writing Your Entry in HTML

Because the *Encyclopedia* is being served over the World Wide Web, all entries must be written in HTML (HyperText Markup Language). This is the formatting language that controls the way text, graphics, and links are displayed in Web browsers. There are now available numerous software programs known as "HTML-editors" or "web authoring tools" and these allow the authors to format text and graphics in HTML easily, without learning any arcane commands. These programs are now as easy to use as Microsoft Word.

To begin writing an entry, authors should follow our instructions for downloading the sourcefile of the "Entry Template". Once the template is downloaded, the author may simply "Open" that file using an HTML-editor. This Entry Template will ensure that there is a uniform entry style, which is described below, in the section on "Entry Format".

For those authors who prefer to create an HTML sourcefile directly, without the assistance of an HTML-editor, we've indicated, in our instructions, how to obtain the "Annotated Sourcefile". After downloading the sourcefile, authors can replace the sample text in this file with their own content. This will minimize the number of HTML commands authors will need to learn.

Note that it is easy to create a link from your main entry to supplementary documents containing overly technical or scholarly material that would interfere with the presentation of the main ideas. To create a link from the main document to a supplementary document, suppose that the main document is entitled "index.html" and the supplementary document is entitled "supplement.html". Now suppose that at the end of a paragraph, you wish place a labeled link to the supplementary document. Here is what the link might be displayed as:

> ... . We discuss this last point in further detail in the following supplementary document:

> Supplement on [Title of Supplement]

Authors using an HTML-editor (such as Netscape Composer, Adobe Page Mill, Front Page Express, etc.) will have to use the functions provided by their software to create such a link. However, authors who can edit their HTML sourcefiles directly would insert the following HTML code in order to produce this link to the supplementary document:

```
...in the following supplementary document.
<blockquote>
<a href="supplement.html" name="return-1">Supplement on [Title of Supplement]</a>
</blockquote>
```

Note that this can be done in other places in your main document, if you have more than one supplementary document. (You will have to name your supplements as "supplement1.html", "supplement2.html", etc.) You can find the sourcefile for the supplement template here (use the View Source function of your browser after following this link).

Entry Format

The Entry Template and Annotated Sourcefile are formatted in HTML so that the following divisions are preserved in every entry:

- Introduction (Definition)
- Internal Links
- Main Sections of the Entry
- Bibliography
- Other Internet Resources
- Related Entries

These are discussed in turn.

Introduction. The Introduction should contain a brief definition of the subject. This may take one or two paragraphs, and if possible, these paragraphs should contain some statement of the subject's interest and significance. The main topics to be covered in the body of the entry may be mentioned here, so that the reader will get some idea of what is to follow.

Internal Links. The internal links should be a list of the main sections of the entry, and each item in the list should be a link to that section. The HTML commands needed to do this are included in the template and in the annotated sourcefile.

Main Sections. The sectioning of the entry is at the discretion of the author. However, we encourage

authors to include a Chronology or "Life" section in Biographical entries. Moreover, a "History" section is called for in the discussion of many topics.

Bibliography. Please use the following bibliographic format:

- Dodgson, H., 1885, ‘The Evidence for the Existence of Snarks’, *Journal of Ornithology,* 25: 22-44
- Hanes, A., 1999a, *Deliverance from Evil Bandersnatches,* London: Houghton & Miflin
- -----, (ed.), 1999b, *Papers on Alice*, Penrith: Bilgewater Press
- Madsen, B., 1924, ‘Slithy Toves’, in *History of Poetry*, S. Johnson (ed.), Cambridge: Cambridge University Press
- Terrell, N., 1888, ‘How to Gimble’, Paris: Longine; page reference is to the reprint in Hanes 1999b.

With this style of Bibliography, you can then cite these sources in your main text with the indication "(Dodson 1885, 32-33)".

Please note: (1) The Bibliography section may be divided into subsections such as Primary Literature and Secondary Literature, or References Cited and Other Important Works, etc. and (2) he Bibliography is reserved primarily for *refereed* material, whether print-based or on the web. Books, journal articles, e-journal articles, etc., which have undergone the normal referee process of legitimate presses should be included. Whenever a cited article or book is available online, a link may be included to the URL.

Other Internet Resources. The author should cite material on the web that is of excellent value but which may not have undergone a referee process. The author serves as referee for these materials (and our subject editors will referee these choices). To complete this section, authors are encouraged to conduct an on-line search of the Web for websites with *high-quality, academic content* on the topic in question. Such websites should be written and maintained by qualified individuals having a clear expertise on the topic. The task of finding such external websites is made considerably simpler by using the Limited Area Search Engines for philosophy, such as Hippias and Noesis. They can be found at the URLs:

> http://hippias.evansville.edu/
> http://noesis.evansville.edu

If this doesn't yield any results, you should try one of the wider area search engines, such as Google or Alta Vista, which can be found at:

> http://www.google.com/
> http://www.altavista.com/

Other search engines include www.lycos.com and www.yahoo.com. Please do not create links to websites that are not maintained by qualified individuals.

Related Entries. Please list the names of the most important concepts and philosophers that occur in your entry. You may list keywords that do not appear as topics in our Table of Contents if you feel that they are important. We are running software which will notice the discrepancy and alert the Editor. A decision will be made whether or not to include a new entry on that topic. If we decide that the topic is too specialized or otherwise inappropriate for the *Encyclopedia*, we will eliminate this keyword from your list in the Related Entries section.

Entry Revision

Because the *Encyclopedia* is designed to be a dynamic reference work, authors are responsible for maintaining and periodically updating their entries. Specifically, authors are expected: (1) to update their entries regularly, especially in response to important new research on the topic of the entry, and (2) to revise their entries *in a timely way* in light of any valid criticism they receive, whether it comes from the subject editors on our Editorial Board, other members of the profession, or interested readers. In connection with (1), authors should update the Bibliography and the Other Internet Resources sections of their entries regularly, to keep pace with significant new publications, both in print and on the web. In connection with (2), the validity of criticism shall be determined by the Editor, typically in consultation with the relevant members of the Editorial Board. The length of time required for a "timely" revision will be negotiable and will both respect the author's current commitments and reflect the seriousness of the criticism. However, entries which require revision but which are not revised within the negotiated timetable may be retired from the active portion of the *Encyclopedia* and left in the *Encyclopedia* Archives until such time as the entry is revised so as to engage the valid criticisms in question.

Making Modifications: There is a preferred, recommended, and easy to use protocol for making changes to your entry. If you would like to add/revise a paragraph, add an item to the Bibliography, fix a typo, etc., the the proper procedure to follow is to log in to our Author Area:

> http://plato.stanford.edu/cgi-bin/encyclopedia/authors.cgi

and initiate the action "Revise Entry on Server". This will allow you to directly edit a copy of your entry on our machine (from whichever browser you are using). There is an Instructions/Help file for using this software. However, as you will see, when you use the Revise Entry function, you will be prompted to select the file you wish to edit. In most cases, you will select the main document, which is called "index.html" (some entries have multiple files, e.g., a main document "index.html" and supplementary documents). Once you have made your selection, a new window will open on your browser and you will be presented with a page on which the file you wanted to edit is divided up into segments, each containing a "View" box and an "Edit" box. You will find the material you wish to edit in the View box, since the text in this box is rendered, or formatted, HTML. Then you edit in the corresponding "Edit" box, which contains the HTML sourcefile (which is plain text with markup tags). It should be clear how add content in the Edit box. Every so often, you should SAVE your work, using the Save buttons at the left or at the top of the page. You may SAVE your work without submitting it for review, but when you

believe you have completed the revisions you need to make, use the Save/Submit option, or return to the authors main menu page and use the Submit/Resubmit Privates Files to Editor function.

Making Major Modifications: There are only two conditions under which it is acceptable to follow a somewhat different procedure. (1) If you know the difference between a simple text editor and an HTML-editor, and you know that your simple text editor can be used to edit an HTML sourcefile without damaging or rewriting the HTML, then you may use the Download Existing Entry File function, edit the file using your simple text editor in plain text mode, save as plain text, and then reupload the file. (2) If you need to make major modifications to your entry, such as a structural reorganization, then it may be inappropriate to use the Revise Entry on Server function. In this case, you would use the Download Existing File function and edit it locally on your computer. However, before you begin to make major modifications to your entry (e.g., by downloading and editing locally), please note that many HTML-editors (Word, Netscape Composer, Dreamweaver, Adobe Page Mill, etc.) do not follow international standards for producing correct HTML. Some add special control characters to the file; others make changes to the HTML, following their own conception of how HTML should be written. So, if you can, please make major modifications to your entry by using a *simple text editor* and by saving the file as plain text (an HTML file is a plain text file in which special pieces of plain text, e.g., "tags" such as <em>, are used to "markup the text" in a way that gives formatting instructions to the web browser). Though a simple text editor will show you all the HTML markup tags, it should be easy to find your way around the file and edit the portions you are interested in. By using a simple text editor, you save us the trouble of having to reprocess (sometimes by hand) the HTML produced by these unfriendly HTML-editors.

After after editing your file, it should then be uploaded back to the *Encyclopedia* by using our Author Area and the "Upload Single File" action.

The Use of Footnotes

Footnotes may be included. Then can often help to shorten the main page of the entry, to make it more readable. The footnotes themselves should be put into a separate html file called "notes.html" and these should be placed into the same directory on plato.stanford.edu as the entry. If you are using an HTML-editor to create your entry, then you will need to use the functions provided by your software in order to create foonotes as links to a footnote file.

However, for those authors who wish to edit their HTML sourcefile directly in order to create links from the text to the footnotes, here are some guidelines to follow. Suppose you want to add footnote number *x* at a point in the text:

> ...some text.[x]

To produce this in your HTML sourcefile, use the following HTML code at the point in the text where

the footnote should occur:

```
...some text.<sup>[<a href="notes.html#x" name="note-x">x</a>]</sup>
```

This will place "[x]" as a superscript in the text, with "x" a link to the place in the notes.html file identified as name="x" (see below). The name="note-x" marks the spot in the current file to which a "Return" link from the notes.html file will return (again, see below). Then, create another HTML file named "notes.html" and in that file you will try to produce something that looks like this:

> x. Begin the body of the footnote here.

To produce this line in the notes.html file, you would add the following HTML code:

```
<p>
<a href="index.html#note-x" name="x">x.</a> Begin the body of the footnote.
```

This will start a new paragraph, start the footnote with the symbols "x." ("x." will be a link back to name="note-x" in the main index.html file; the name="x" identifies the place in the notes.html file to which the footnote in the main text will be linked). Note: Users of the *Encyclopedia* can always use the "Back" or "Return" button on their browsers to get back to the text.

The Use of Special Symbols

Although the specifications for the HTML4.0 language does include support for a variety of special symbols, including Greek, logic and math symbols, there is little support for arranging these symbols on the page in the variety of ways needed by mathematicians and logicians. A new standard for typesetting mathematical and logical formulas is developing, namely, MathML. See W3C Math: MathML puts Math on the Web. However, it will be sometime before web browsers are reprogrammed to meet this standard. So, for now, we would ask you not to employ the MathML standard or the symbols that are supported in HTML4.0.

In the meantime, if the special symbol you need is not on this list of special HTML characters which is widely supported, we have created a wide variety of small graphics of the Greek, logic, and math symbols that logicians and others typically use. These symbols are located at the URL:

> http://plato.stanford.edu/symbols/

For example, we have produced the following graphic of the symbol for the "set membership" relation:

> $\in$

This symbol can be found at the URL displayed above and you can download it onto your machine from there. Follow the link to "element.gif" in the table for Math symbols. You can then save that graphic onto the drive of your local computer.

If you are using an HTML-editor to create your entry, then you simply use your software's "add image" ("add graphic") function to place this graphic in your entry. However, those authors who are editing their HTML sourcefiles directly should use the following guidelines. To produce the formatted line:

$x \in y$

place the file "element.gif" into the directory containing your HTML entry and use the following HTML code in your entry:

```
<em>x</em> <img src="element.gif"> <em>y</em>
```

Note that you will not need to transfer the graphics to the same directory on plato when you transfer your entry to us -- the first time you view your file on our server after uploading it, our software will recognize the links to our graphics and it will automatically install copies of the needed graphic files into your upload directory.

You may use any graphic found in our symbols directory in this way. If you need a symbol not found in that directory, write to the editor---they are easily constructed.

Snark

Snarks are a species of bandersnatch. They are thought to have evolved from the slithy toves along with the other bandersnatches. Snarks were common in New England forests until the late 19th century, when it was thought that they were hunted to extinction. Recent ethological expeditions, however, have uncovered evidence that there may be a few extant individuals. Snarks are favorites with animal lovers everywhere because in the spring, they gyre and gimble on small ponds in a brilliant mating display. In reference works on bandersnatches, snarks are referred to as a group by the Latin name *Snarkidae*.

Evolutionary History and Adaptive Features

Snarks are a species of bandersnatch and are thought to have evolved from the slithy toves along with the other bandersnatches. Snarks evolved in the Devonian period and successfully adapted themselves in several ecological niches until the late 19th century. The fact that they have a dorsal sigmoid bone establishes their descent from the slithy toves.

Snarks bear young just at the point in early summer when their food source is most abundant. Their biological clocks are very well tuned and biologists study them as the principal model of such clocks in the animal kingdom.

Mating Display

There is nothing like the wonder and pageantry of snarks in mating season, as they gyre and gimble on the ponds of New England forests.

Pascal's Wager

"Pascal's Wager" is the name given to an argument due to Blaise Pascal for believing, or for at least taking steps to believe, in God. The name is somewhat misleading, for in a single paragraph of his *Pensées*, Pascal apparently presents at least *three* such arguments, each of which might be called a ‘wager’---it is only the final of these that is traditionally referred to as "Pascal's Wager". We find in it the extraordinary confluence of several strands in intellectual thought: the justification of theism; probability theory and decision theory, used here for almost the first time in history; pragmatism; voluntarism (the thesis that belief is a matter of the will); and the use of the concept of infinity.

We will begin with some brief stage-setting: some historical background, some of the basics of decision theory, and some of the exegetical problems that the *Pensées* pose. Then we will follow the text to extract three main arguments. The bulk of the literature addresses the third of these arguments, as will the bulk of our discussion here. Some of the more technical and scholarly aspects of our discussion will be relegated to lengthy footnotes, to which there are links for the interested reader. All quotations are from §233 of *Pensées* (1910, Trotter translation), the ‘thought’ whose heading is "*Infinite---nothing*".

---

1. Background

It is important to contrast Pascal's argument with various putative ‘proofs’ of the existence of God that had come before it. Anselm's ontological argument, Aquinas' ‘five ways’, Descartes' ontological and cosmological arguments, and so on, purport to give *a priori* demonstrations that God exists. Pascal is apparently unimpressed by such attempted justifications of theism: "Endeavour ... to convince yourself,

not by increase of proofs of God..." Indeed, he concedes that "we do not know if He is ...". Pascal's project, then, is radically different: he seeks to provide *prudential* reasons for believing in God. To put it crudely, we should wager that God exists because it is the *best bet*. Ryan 1994 finds precursors to this line of reasoning in the writings of Plato, Arnobius, Lactantius, and others; we might add Ghazali to his list---see Palacios 1920. But what is distinctive is Pascal's explicitly decision theoretic formulation of the reasoning. In fact, Hacking 1975 describes the Wager as "the first well-understood contribution to decision theory" (viii). Thus, we should pause briefly to review some of the basics of that theory.

In any decision problem, the way the world is, and what an agent does, together determine an outcome for the agent. We may assign *utilities* to such outcomes, numbers that represent the degree to which the agent values them. It is typical to present these numbers in a decision matrix, with the columns corresponding to the various relevant states of the world, and the rows corresponding to the various possible actions that the agent can perform.

In *decisions under uncertainty*, nothing more is given---in particular, the agent does not assign subjective probabilities to the states of the world. Still, sometimes rationality dictates a unique decision nonetheless. Consider, for example, a case that will be particularly relevant here. Suppose that you have two possible actions, A1 and A2, and the worst outcome associated with A1 is at least as good as the best outcome associated with A2; suppose also that in at least one state of the world, A1's outcome is strictly better than A2's. Let us say in that case that A1 *superdominates* A2. Then rationality surely requires you to perform A1.

In *decisions under risk*, the agent assigns subjective probabilities to the various states of the world. Assume that the states of the world are independent of what the agent does. A figure of merit called the *expected utility*, or the *expectation* of a given action can be calculated by a simple formula: for each state, multiply the utility that the action produces in that state by the state's probability; then, add these numbers. According to decision theory, rationality requires you to perform the action of maximum expected utility (if there is one).

Example. Suppose that the utility of money is linear in number of dollars: you value money at exactly its face value. Suppose that you have the option of paying a dollar to play a game in which there is an equal chance of returning nothing, and returning three dollars. The expectation of the game itself is

$$0*(1/2) + 3*(1/2) = 1.5,$$

so the expectation of paying a dollar for certain, then playing, is

$$-1 + 1.5 = 0.5.$$

This exceeds the expectation of not playing (namely 0), so you should play. On the other hand, if the game gave an equal chance of returning nothing, and returning two dollars, then its expectation would be:

> 0*(1/2) + 2*(1/2) = 1.

Then consistent with decision theory, you could either pay the dollar to play, or refuse to play, for either way your overall expectation would be 0.

Considerations such as these will play a crucial role in Pascal's arguments. It should be admitted that there are certain exegetical problems in presenting these arguments. Pascal never finished the *Pensées*, but rather left them in the form of notes of various sizes pinned together. Hacking 1972 describes the "Infinite---nothing" as consisting of "two pieces of paper covered on both sides by handwriting going in all directions, full of erasures, corrections, insertions, and afterthoughts" (24).[1] This may explain why certain passages are notoriously difficult to interpret, as we will see. Furthermore, our formulation of the arguments in the parlance of modern Bayesian decision theory might appear somewhat anachronistic. For example, Pascal did not distinguish between what we would now call *objective* and *subjective* probability, although it is clear that it is the latter that is relevant to his arguments. To some extent, "Pascal's Wager" now has a life of its own, and our presentation of it here is perfectly standard. Still, we will closely follow Pascal's text, supporting our reading of his arguments as much as possible.

There is the further problem of dividing the *Infinite-nothing* into separate arguments. We will locate three arguments that each conclude that rationality requires you to wager for God, although they interleave in the text.[2] Finally, there is some disagreement over just what "wagering for God" involves---is it *believing* in God, or merely *trying* to? We will conclude with a discussion of what Pascal meant by this.

2. The Argument from Superdominance

Pascal maintains that we are incapable of knowing whether God exists or not, yet we must "wager" one way or the other. Reason cannot settle which way we should incline, but a consideration of the relevant outcomes supposedly can. Here is the first key passage:

> "God is, or He is not." But to which side shall we incline? Reason can decide nothing here. There is an infinite chaos which separated us. A game is being played at the extremity of this infinite distance where heads or tails will turn up... Which will you choose then? Let us see. Since you must choose, let us see which interests you least. You have two things to lose, the true and the good; and two things to stake, your reason and your will, you knowledge and your happiness; and your nature has two things to shun, error and misery. Your reason is no more shocked in choosing one rather than the other, since you must of necessity choose... But your happiness? Let us weigh the gain and the loss in wagering that God is... If you gain, you gain all; if you lose, you lose nothing. Wager, then, without hesitation that He is.

There are exegetical problems already here, partly because Pascal appears to contradict himself. He speaks of "the true" as something that you can "lose", and "error" as something "to shun". Yet he goes on

to claim that if you lose the wager that God is, then "you lose nothing". Surely in that case you "lose the true", which is just to say that you have made an error. Pascal believes, of course, that the existence of God is "the true"---but *that* is not something that he can appeal to in this argument. Moreover, it is not because "you must of necessity choose" that "your reason is no more shocked in choosing one rather than the other". Rather, by Pascal's own account, it is because "[r]eason can decide nothing here". (If it could, then it might well be shocked - namely, if you chose in a way contrary to it.)

Following McClennen 1994, Pascal's argument seems to be best captured as presenting the following decision matrix:

	God exists	***God does not exist***
Wager for God	Gain all	Status quo
Wager against God	Misery	Status quo

Wagering for God superdominates wagering against God: the worst outcome associated with wagering for God (status quo) is at least as good as the best outcome associated with wagering against God (status quo); and if God exists, the result of wagering for God is strictly better that the result of wagering against God. (The fact that the result is *much* better does not matter yet.) Pascal draws the conclusion at this point that rationality requires you to wager for God.

Without any assumption about your probability assignment to God's existence, the argument is invalid. Rationality does *not* require you to wager for God if you assign probability 0 to God existing. And Pascal does not explicitly rule this possibility out until a later passage, when he assumes that you assign positive probability to God's existence; yet this argument is presented as if it is self-contained. His claim that "[r]eason can decide nothing here" may suggest that Pascal regards this as a decision under uncertainty, which is to assume that you do *not* assign probability at all to God's existence. If that is a further premise, then the argument is valid; but that premise contradicts his subsequent assumption that you assign positive probability. See McClennen for a reading of this argument as a decision under uncertainty.

Pascal appears to be aware of a further objection to this argument, for he immediately imagines an opponent replying:

> "That is very fine. Yes, I must wager; but I may perhaps wager too much."

The thought seems to be that if I wager for God, and God does not exist, then I really do lose something. In fact, Pascal himself speaks of *staking something* when one wagers for God, which presumably one loses if God does not exist. (We have already mentioned ‘the true’ as one such thing; Pascal also seems to regard one's worldly life as another.) In other words, the matrix is mistaken in presenting the two outcomes under ‘God does not exist’ as if they were the same, and we do not have a case of superdominance after all.

Pascal addresses this at once in his second argument, which we will discuss only briefly, as it can be thought of as just a prelude to the main argument.

3. The Argument From Expectation

He continues:

> Let us see. Since there is an equal risk of gain and of loss, if you had only to gain two lives, instead of one, you might still wager. But if there were three lives to gain, you would have to play (since you are under the necessity of playing), and you would be imprudent, when you are forced to play, not to chance your life to gain three at a game where there is an equal risk of loss and gain. But there is an eternity of life and happiness.

His hypothetically speaking of "two lives" and "three lives" may strike one as odd. It is helpful to bear in mind Pascal's interest in gambling (which after all provided the initial motivation for his study of probability) and to take the gambling model quite seriously here. Recall our calculation of the expectations of the two dollar and three dollar gambles. Pascal apparently assumes now that utility is linear in number of *lives*, that wagering for God costs "one life", and then reasons analogously to the way we did! This is, as it were, a warm-up. Since wagering for God is rationally required even in the hypothetical case in which one of the prizes is three lives, then all the more it is rationally required in the actual case, in which one of the prizes is *eternal* life (salvation).

So Pascal has now made two striking assumptions:

> (1) The probability of God's existence is 1/2.
> (2) Wagering for God brings *infinite* reward if God exists.

Morris 1994 is sympathetic to (1), while Hacking 1972 finds it "a monstrous premiss". It apparently derives from the classical interpretation of probability, according to which all possibilities are given equal weight. Of course, unless more is said, the interpretation yields implausible, and even contradictory results. (You have a one-in-a-million chance of winning the lottery; but either you win the lottery or you don't, so each of these possibilities has probability 1/2?!) Pascal's best argument for (1) is presumably that "[r]eason can decide nothing here". (In the lottery ticket case, reason can decide *something*.) But it is not clear that complete ignorance should be modeled as sharp indifference. In any case, it *is* clear that there are people in Pascal's audience who do not assign probability 1/2 to God's existence. This argument, then, does not speak to them.

However, Pascal realizes that the value of 1/2 actually plays no real role in the argument, thanks to (2). This brings us to the third, and by far the most important, of his arguments.

4. The Argument From Generalized Expectations:

"Pascal's Wager"

We continue the quotation.

> But there is an eternity of life and happiness. And this being so, if there were an infinity of chances, of which one only would be for you, you would still be right in wagering one to win two, and you would act stupidly, being obliged to play, by refusing to stake one life against three at a game in which out of an infinity of chances there is one for you, if there were an infinity of an infinitely happy life to gain. But there is here an infinity of an infinitely happy life to gain, a chance of gain against a finite number of chances of loss, and what you stake is finite. It is all divided; wherever the infinite is and there is not an infinity of chances of loss against that of gain, there is no time to hesitate, you must give all...

Again this passage is difficult to understand completely. Pascal's talk of winning two, or three, lives is at best misleading. By his own decision theoretic lights, you would *not* act stupidly "by refusing to stake one life against three at a game in which out of an infinity of chances there is one for you"---in fact, you should not stake more than an infinitesimal amount in that case (an amount that is bigger than 0, but smaller than every positive real number). The point, rather, is that the prospective prize is "an infinity of an infinitely happy life". In short, if God exists, then wagering for God results in infinite utility.

What about the utilities for the other possible outcomes? There is some dispute over the utility of "misery". Hacking interprets this as "damnation", and Pascal does later speak of "hell" as the outcome in this case. Martin 1983 among others assigns this a value of *negative infinity*. Sobel 1996, on the other hand, is one author who takes this value to be finite. There is some textual support for this reading: "The justice of God must be vast like His compassion. Now justice to the outcast is less vast ... than mercy towards the elect". As for the utilities of the outcomes associated with God's non-existence, Pascal tells us that "what you stake is finite". This suggests that whatever these values are, they are finite.

Pascal's guiding insight is that the argument from expectation goes through equally well *whatever* your probability for God's existence is, provided that it is non-zero and finite (non-infinitesimal)---"a chance of gain against a finite number of chances of loss".[3]

With Pascal's assumptions about utilities and probabilities in place, he is now in a position to calculate the relevant expectations. He explains how the calculations should proceed:

> ... the uncertainty of the gain is proportioned to the certainty of the stake according to the proportion of the chances of gain and loss... [4]

Let us now gather together all of these points into a single argument. We can think of Pascal's Wager as having three premises: the first concerns the decision matrix of rewards, the second concerns the

probability that you should give to God's existence, and the third is a maxim about rational decision-making. Specifically:

1. Either God exists or God does not exist, and you can either wager for God or wager against God. The utilities of the relevant possible outcomes are as follows, where f_1, f_2, and f_3 are numbers whose values are not specified beyond the requirement that they be finite:

	God exists	***God does not exist***
Wager for God	∞	f_1
Wager against God	f_2	f_3

2. Rationality requires the probability that you assign to God existing to be positive, and not infinitesimal.
3. Rationality requires you to perform the act of maximum expected utility (when there is one).
4. Conclusion 1. Rationality requires you to wager for God.
5. Conclusion 2. You should wager for God.

We have a decision under risk, with probabilities assigned to the relevant ways the world could be, and utilities assigned to the relevant outcomes. The conclusion seems straightforwardly to follow from the usual calculations of expected utility (where p is your positive, non-infinitesimal probability for God's existence):

$$E(\text{wager for God}) = \infty * p + f_1 * (1 - p) = \infty$$

That is, your expected utility of belief in God is infinite---as Pascal puts it, "our proposition is of infinite force". On the other hand, your expected utility of wagering against God is

$$E(\text{wager against God}) = f_2 * p + f_3 * (1 - p)$$

This is finite.[5] By premise 3, rationality requires you to perform the act of maximum expected utility. Therefore, rationality requires you to wager for God.

We now survey some of the main objections to the argument.

5. Objections to Pascal's Wager

Premise 1: The Decision Matrix

Here the objections are manifold. Most of them can be stated quickly, but we will give special attention to what has generally been regarded as the most important of them, ‘the many Gods objection’ (see also the link to footnote 7).

1. Different matrices for different people. The argument assumes that the same decision matrix applies to everybody. However, perhaps the relevant rewards are different for different people. Perhaps, for example, there is a predestined infinite reward for the Chosen, whatever they do, and finite utility for the rest, as Mackie 1982 suggests. Or maybe the prospect of salvation appeals more to some people than to others, as Swinburne 1969 has noted.

Even granting that a single 2 x 2 matrix applies to everybody, one might dispute the values that enter into it. This brings us to the next two objections.

2. The utility of salvation could not be infinite. One might argue that the very notion of infinite utility is suspect---see for example Jeffrey 1983 and McClennen 1994.[6] Hence, the objection continues, whatever the utility of salvation might be, it must be finite. Strict finitists, who are chary of the notion of infinity in general, will agree---see. Dummett 1978 and Wright 1987. Or perhaps the notion of infinite utility makes sense, but an infinite reward could only be finitely appreciated by a human being.

3. There should be more than one infinity in the matrix. There are also critics of the Wager who, far from objecting to infinite utilities, want to see *more* of them in the matrix. For example, it might be thought that a forgiving God would bestow infinite utility upon wagerers-for and wagerers-against alike---Rescher 1985 is one author who entertains this possibility. Or it might be thought that, on the contrary, wagering against an existent God results in *negative* infinite utility. (As we have noted, some authors read Pascal himself as saying as much.) Either way, f_2 is not really finite at all, but ∞ or $-\infty$ as the case may be. And perhaps f_1 and f_3 could be ∞ or $-\infty$. Suppose, for instance, that God does not exist, but that we are reincarnated *ad infinitum*, and that the total utility we receive is an infinite sum that does not converge.

4. The matrix should have more rows. Perhaps there is more than one way to wager for God, and the rewards that God bestows vary accordingly. For instance, God might not reward infinitely those who strive to believe in Him only for the very mercenary reasons that Pascal gives, as James 1956 has observed. One could also imagine distinguishing belief based on faith from belief based on evidential reasons, and posit different rewards in each case.

5. The matrix should have more columns: the many Gods objection. If Pascal is really right that reason can decide nothing here, then it would seem that various other theistic hypotheses are also live options. Pascal presumably had in mind the Catholic conception of God---let us suppose that this is the God who either ‘exists’ or ‘does not exist’. By excluded middle, this is a partition. The objection, then, is that the partition is not sufficiently fine-grained, and the ‘(Catholic) God does not exist’ column really subdivides into various *other* theistic hypotheses. The objection could equally run that Pascal's argument ‘proves too much’: by parallel reasoning we can ‘show’ that rationality requires believing in various incompatible

theistic hypotheses. As Diderot 1875-77 puts the point: "An Imam could reason just as well this way".[7]

Since then, the point has been represented and refined in various ways. Mackie 1982 writes, "the church within which alone salvation is to be found is not necessarily the Church of Rome, but perhaps that of the Anabaptists or the Mormons or the Muslim Sunnis or the worshippers of Kali or of Odin" (203). Cargile 1966 shows just how easy it is to multiply theistic hypotheses: for each real number *x*, consider the God who prefers contemplating *x* more than any other activity. It seems, then, that such ‘alternative gods’ are a dime a dozen---or aleph one, for that matter.

Premise 2: The Probability Assigned to God's Existence

There are four sorts of problem for this premise. The first two are straightforward; the second two are more technical, and can be found by following the link to footnote 8.

1. Undefined probability for God's existence. Premise 1 presupposes that you should *have* a probability for God's existence in the first place. However, perhaps you could rationally *fail* to assign it a probability---your probability that God exists could remain *undefined*. We cannot enter here into the thorny issues concerning the attribution of probabilities to agents. But there is some support for this response even in Pascal's own text, again at the pivotal claim that "[r]eason can decide nothing here. There is an infinite chaos which separated us. A game is being played at the extremity of this infinite distance where heads or tails will turn up..." The thought could be that any probability assignment is inconsistent with a state of "epistemic nullity" (in Morris' 1986 phrase): to assign a probability at all---even 1/2---to God's existence is to feign having evidence that one in fact totally lacks. For unlike a coin that we know to be fair, this metaphorical ‘coin’ is ‘infinitely far’ from us, hence apparently completely unknown to us. Perhaps, then, rationality actually requires us to *refrain* from assigning a probability to God's existence (in which case at least the Argument from Superdominance would be valid). Or perhaps rationality does not require it, but at least *permits* it. Either way, the Wager would not even get off the ground.

2. Zero probability for God's existence. Strict atheists may insist on the rationality of a probability assignment of 0, as Oppy 1990 among others points out. For example, they may contend that reason alone *can* settle that God does not exist, perhaps by arguing that the very notion of an omniscient, omnipotent, omnibenevolent being is contradictory. Or a Bayesian might hold that rationality places no constraint on probabilistic judgments beyond coherence (or conformity to the probability calculus). Then as long as the strict atheist assigns probability 1 to God's non-existence alongside his or her assignment of 0 to God's existence, no norm of rationality has been violated.

Furthermore, an assignment of p = 0 would clearly block the route to Pascal's conclusion. For then the expectation calculations become:

$$E(\text{wager for God}) = \infty * 0 + f_1 * (1 - 0) = f_1$$

$$E(\text{wager against God}) = f_2{*}0 + f_3{*}(1 - 0) = f_3$$

And nothing in the argument implies that $f_1 > f_3$. (Indeed, this inequality is questionable, as even Pascal seems to allow.) In short, Pascal's wager has no pull on strict atheists.[8]

Premise 3: Rationality Requires Maximizing Expected Etility

Finally, one could question Pascal's decision theoretic assumption that rationality requires one to perform the act of maximum expected utility (when there is one). Now *perhaps* this is an analytic truth, in which case we could grant it to Pascal without further discussion---perhaps it is *constitutive* of rationality to maximize expectation, as some might say. But this premise has met serious objections. The Allais 1953 and Ellsberg 1961 paradoxes, for example, are said to show that maximizing expectation can lead one to perform intuitively sub-optimal actions. So too the St. Petersburg paradox, in which it is supposedly absurd that one should be prepared to pay any finite amount to play a game with infinite expectation. (That paradox is particularly apposite here.)[9]

Finally, one might distinguish between *practical* rationality and *theoretical* rationality. One could then concede that practical rationality requires you to maximize expected utility, while insisting that theoretical rationality might require something else of you---say, proportioning belief to the amount of evidence available. This objection is especially relevant, since Pascal admits that perhaps you "must renounce reason" in order to follow his advice. But when these two sides of rationality pull in opposite directions, as they apparently can here, it is not obvious that practical rationality should take precedence. (For a discussion of pragmatic, as opposed to theoretical, reasons for belief, see Foley 1994.)

Is the Argument Valid?

A number of authors who have been otherwise critical of the Wager have explicitly conceded that the Wager is valid---e.g. Mackie 1982, Rescher 1985, Mougin and Sober 1994, and most emphatically, Hacking 1972. That is, these authors agree with Pascal that wagering for God really is rationally mandated by Pascal's decision matrix in tandem with positive probability for God's existence, and the decision theoretic account of rational action.

However, Duff 1986 and Hájek 2001 argue that the argument is in fact invalid. Their point is that there are strategies besides wagering for God that also have infinite expectation---namely, *mixed* strategies, whereby you do not wager for or against God outright, but rather choose which of these actions to perform on the basis of the outcome of some chance device. Consider the mixed strategy: "Toss a fair coin: heads, you wager for God; tails, you wager against God". By Pascal's lights, with probability 1/2 your expectation will be infinite, and with probability 1/2 it will be finite. The expectation of the entire strategy is:

$$1/2{*}\infty + 1/2[f_2{*}p + f_3{*}(1 - p)] = \infty$$

That is, the ‘coin toss’ strategy has the same expectation as outright wagering for God. But the probability 1/2 was incidental to the result. Any mixed strategy that gives positive and finite probability to wagering for God will likewise have infinite expectation: "wager for God iff a fair die lands 6", "wager for God iff your lottery ticket wins", "wager for God iff a meteor quantum tunnels its way through the side of your house", and so on.

The problem is still worse than this, though, for there is a sense in which *anything* that you do might be regarded as a mixed strategy between wagering for God, and wagering against God, with suitable probability weights given to each. Suppose that you choose to ignore the Wager, and to go and have a hamburger instead. Still, you may well assign positive and finite probability to your winding up wagering for God nonetheless; and this probability multiplied by infinity again gives infinity. So ignoring the Wager and having a hamburger has the same expectation as outright wagering for God. Even worse, suppose that you focus all your energy into *avoiding* belief in God. Still, you may well assign positive and finite probability to your efforts failing, with the result that you wager for God nonetheless. In that case again, your expectation is infinite again. So even if rationality requires you to perform the act of maximum expected utility when there is one, here there isn't one. Rather, there is a many-way tie for first place, as it were.[10]

Moral Objections to Wagering for God

Let us grant Pascal's conclusion for the sake of the argument: rationality requires you to wager for God. It still does not obviously follow that you *should* wager for God. All that we have granted is that one norm---the norm of rationality---prescribes wagering for God. For all that has been said, some *other* norm might prescribe wagering against God. And unless we can show that the rationality norm trumps the others, we have not settled what we should actually do.

There are several arguments to the effect that *morality* requires you to wager against God. Pascal himself appears to be aware of one such argument. He admits that if you do not believe in God, his recommended course of action will "deaden your acuteness." One way of putting the argument is that wagering for God may require you to corrupt yourself, thus violating a Kantian duty to yourself. Clifford 1986 argues that an individual's believing something on insufficient evidence harms society by promoting credulity. Penelhum 1971 contends that the putative divine plan is itself immoral, condemning as it does honest non-believers to loss of eternal happiness, when such unbelief is in no way culpable; and that to adopt the relevant belief is to be complicit to this immoral plan. See Quinn 1994 for replies to these arguments. For example, against Penelhum he argues that as long as God treats non-believers justly, there is nothing immoral about him bestowing special favor on believers, more perhaps than they deserve. (Note, however, that Pascal leaves open in the Wager whether the payoff for non-believers *is* just, even though as far as his argument goes, it may be extremely poor.)

Finally, Voltaire protests that there is something unseemly about the whole Wager. He suggests that Pascal's calculations, and his appeal to self-interest, are unworthy of the gravity of the subject of theistic

belief. This does not so much support wagering against God, as dismissing all talk of ‘wagerings’ altogether.

What Does It Mean to "Wager for God"?

Let us now grant Pascal that, all things considered (rationality and morality included), you should wager for God. What exactly does this involve?

A number of authors read Pascal as arguing that you should *believe* in God---see e.g. Quinn 1994, and Jordan 1994a. But perhaps one cannot simply believe in God at will; and rationality cannot require the impossible. Pascal is well aware of this objection: "[I] am so made that I cannot believe. What, then, would you have me do?", says his imaginary interlocutor. However, he contends that one can take steps to cultivate such belief:

> You would like to attain faith, and do not know the way; you would like to cure yourself of unbelief, and ask the remedy for it. Learn of those who have been bound like you, and who now stake all their possessions. These are people who know the way which you would follow, and who are cured of an ill of which you would be cured. Follow the way by which they began; by acting as if they believed, taking the holy water, having masses said, etc...
>
> But to show you that this leads you there, it is this which will lessen the passions, which are your stumbling-blocks.

We find two main pieces of advice to the non-believer here: act like a believer, and suppress those passions that are obstacles to becoming a believer. And these are actions that one *can* perform at will.

Believing in God is presumably one way to wager for God. This passage suggests that even the non-believer can wager for God, by striving to become a believer. Critics may question the psychology of belief formation that Pascal presupposes, pointing out that one could strive to believe (perhaps by following exactly Pascal's prescription), yet fail. To this, a follower of Pascal might reply that the act of genuine striving already displays a pureness of heart that God would fully reward; or even that genuine striving in this case is itself a form of believing.

Pascal's Wager vies with Anselm's Ontological Argument for being the most famous argument in the philosophy of religion. As we have seen, it is also a great deal more besides.

Notes to Pascal's Wager

Notes

1. Those interested in the reconstruction over the years of the text itself should consult Lafuma 1954.

2. Our demarcation of the arguments follows that of Hacking 1972, although we will differ on certain points of detail.

3. Unfortunately, he squanders this insight when he lapses back to the assumption that the probability is 1/2 shortly thereafter: "And so our proposition is of infinite force, when there is the finite to stake in a game where there are equal risks of gain and of loss, and the infinite to gain."

4. We know from Pascal's other writings that he understood the decision theoretic formula of expectation. Note, though, that this is a rather curious way of presenting it. Consider a gamble in which there is a probability p of some good outcome g, and probability 1 − p of some bad outcome b. Then the expectation e of the gamble is given by

$$e = g*p + b*(1 - p)$$

Rearranging this, we have:

$$p*(g - e) = (e - b)*(1 - p),$$

or

```
e - b     p
----- = -----
g - e   1 - p
```

That is, compared to the expectation, the shortfall of the bad outcome is proportioned to surplus of the good outcome according to the proportion of the chances of gain and loss. It is not obvious that this amounts to the same thing as what Pascal says.

5. In the basic version of decision theory that we have presented, states are assumed to be independent of actions. Evidential decision theory generalizes this. It replaces in its expectation calculation for a given

action the unconditional probabilities of states by the conditional probabilities of the states, given the action---see Jeffrey 1983. Now perhaps what you do is not independent of whether God exists. For instance, maybe God helps people wager for Him, so that P(God exists|you wager for God) > P(God exists|you wager against God). Still, the expected utility calculations are as before, provided the first conditional probability is positive and finite: infinite for wagering for God, finite for wagering against God.

Causal decision theory replaces evidential decision theory's conditional probabilities with probabilities that capture the degree of causal relevance of an action to each state. There are various versions of causal decision theory---see Lewis 1981. Using some such version would presumably not significantly affect matters here. We would just replace the assumption that your probability is positive and finite with the same assumption about whatever probability is used instead.

6. After all, infinite utilities would run afoul of the Archimedean, or continuity axiom that is commonly assumed in decision theory:

> If you prefer A to B, and prefer B to C, then there is a gamble between A and C (A with probability p, C with probability 1 − p, for some real-valued p) that you regard as equally desirable as B for sure.

For suppose that salvation, say, has infinite utility for you. You prefer salvation to $1, and prefer $1 to nothing; but there is no such gamble that rewards you with salvation if you win, and nothing if you lose, that you value at $1. Indeed, assuming that the probability of winning remains positive, you prefer the gamble to any finite reward; but if the probability of winning drops to 0, your preference discontinuously switches to the finite reward.

The issue then becomes whether continuity is a requirement on rational preference. Hájek 1997a and 2000a argues that it is not, and gives further positive arguments for allowing infinite utilities into decision theory. Sorensen 1994 likewise argues for "infinite decision theory". For a highly technical presentation of ‘non-Archimedean’ decision theory, see Skalia 1975. For related work on infinite utilities that is more philosophical, see Cain 1995, Nelson 1991, Ng 1995, Vallentyne 1993, Vallentyne 1995, Vallentyne and Kagan 1997, and van Liedekerke 1995. Some of the literature on the so-called two-envelope problem is also relevant---see, for example, Broome 1995, Castell and Batens 1994, Chalmers 1997, Jackson et al. 1994, Nalebuff 1989.

7. It should be pointed out that the rival Gods must award infinite utility for salvation in order to create a problem---otherwise they will be trumped by the ones that do. (It seems that Kali and Odin thus drop out of consideration, for example.) And to be damaging to the Wager, the alternative hypotheses about how salvation is achieved should be mutually exclusive. If there is some common core to the theistic hypotheses, and it suffices to (strive to) believe that in order to be saved, then there is no problem. For instance, it will not matter that you do not know what God's favorite real number is, if it turns out that you are saved as long as your belief is adequate in other respects. So it is crucial that salvation hinges on

getting the details of the belief right. What, then, should we believe? To settle this question, it seems we get nowhere with Pascal-style practical reasoning.

One response is that we are therefore in a position somewhat like that of Buridan's ass, unable to settle which course of action is best; and that like the ass we are better off doing something rather than nothing, and in this case that means choosing one of the theistic hypotheses, and hoping we choose the right one. So it might still be rationally required to be a theist. See Jordan 1994a for a version of this "ecumenical" response. There are at least two counter-responses. Firstly, the assumption that there are alternative Gods who offer infinite rewards really plays no role in the many-Gods objection argument. All that matters is that there are sources of infinite reward besides Pascal's God. These sources could even be inanimate---as it might be, supreme pleasure machines, which offer infinite utility irrespective of one's beliefs. Secondly, one of the alternative Gods might punish those who wager for him, and reward those who don't---see Martin's 1983 "perverse master".

At this point it can be replied that these various other hypotheses lack the backing of tradition that genuine religions have, and thus should be disregarded---see especially Jordan 1994a and Schlesinger 1994. More precisely, these other hypotheses should be assigned zero (or perhaps at most infinitesimal) probability, so that they do not upset Pascal's expectation calculations. The debate then turns once again on what exactly rationality requires of one's probability assignments.

8. Here are the third and fourth problems for Premise 2.

3. Infinitesimal probability for God's existence.

One might reply that you can rationally assign infinitesimal probability to God's existence---see e.g. Oppy 1990. The argument might run, for example, that there are infinitely many possible Gods to consider (see our discussion of the many Gods objection), and for some infinite subset of them that includes Pascal's God, rationality does not favor any one over the rest. Treating them even-handedly then requires assigning infinitesimal probability to each. Or again, a Bayesian might say that you could coherently assign to God's existence an infinitesimal probability, provided that you also assign a probability to God's non-existence that falls short of 1 by the same infinitesimal.

It is remarkable that Pascal anticipated the notion of infinitesimal probability, when he says: "if there were an infinity of chances, of which one only would be for you, you would still be right in wagering one [life] ... if there were an infinity of an infinitely happy life to gain." But what he says here is far from obvious. If ∞ is a legitimate utility value, then offhand it would seem that $1/\infty$ is a legitimate probability value, and indeed it seems to be the very one that he is considering. However, then we have:

$$E(\text{wager for God}) = \infty * (1/\infty) + f_1 * [1 - (1/\infty)] \approx 1 + f_1$$

And it is not clear that this should exceed f_3.

All of this treats ∞ as if it is a number, subject to ordinary arithmetic operations, such as taking reciprocals, multiplying and adding. Perhaps, for example, $\infty*(1/\infty)$ is not defined, much as $\infty - \infty$ is not. But that is just another way in which a probability of $(1/\infty)$ might thwart Pascal's reasoning. We will say more below about infinite numbers for which such arithmetic operations are unproblematic.

4. Vague probability for God's existence

So far we have presupposed that probability assignments are sharp. However, Pascal's argument is addressed to us---mere humans. And it is apparently a fact about us that our belief states are irremediably vague: we cannot assign probability, precise to indefinitely many decimal places, to all propositions. Perhaps, then, rationality permits us to assign vague probability to God's existence. If it moreover permits us to assign it probability that is vague over an interval that includes 0, then the Wager fails---see Hájek 2000. Indeed, Pascal's claim that "[reason] can decide nothing here" might be thought to support a probability assignment to God's existence that is vague over the entire [0, 1] interval. [Return to text]

9. One could also insist that rational choices must be ratifiable (à la Jeffrey 1983 or Sobel 1996), and that the act of maximum expectation might not be.

The usual rationale for maximizing expectation comes from the various laws of large numbers. Their content is roughly that under suitable circumstances, in the limit, one's average reward tends to the expectation; and of course one wants to maximize one's average reward. But the strong law of large numbers assumes that the expectation is finite, and since the expectation of wagering for God is putatively infinite, it clearly cannot be appealed to here. (See e.g. Feller 1971, 236.) Perhaps an appeal to the weak law of large numbers, which allows infinite expectation, would suffice. But being a limit theorem, it concerns infinitely long runs of trials. Far from having such a long run here, we have just a single-shot decision problem. This is a decision that you do not get to repeat. This is not so troubling, perhaps, when the variance (a measure of the spread of the distribution of outcomes) is small, so that getting an outcome close to the expectation is probable; but what about when the variance is large?

This brings us to yet another problem for Pascal's third premise. To be sure, the expectation of wagering for God is infinite, if we accept Pascal's earlier assumptions; but so too is the variance. Expectation does not seem to be such a good guide to choiceworthiness when the variance is large---for what one might end up getting can then be much worse than the expectation---let alone when the variance is infinite. (See Weirich 1984 and Sorensen 1994 for versions of this last point.) Indeed, the lower one makes f_2 (or more generally, some highly dispreferred outcome), the less compelling premise 3 seems; and the lower one makes the probability of salvation (or more generally, of some highly desired outcome), the less compelling premise 3 seems. Yet consistent with premise 1, f_2 could be (almost) as low as one likes, and consistent with premise 2, the probability of salvation could be (almost) as low as one likes.

10. Schlesinger 1994 offers a tie-breaking criterion: "try and increase the probability of obtaining the prospective prize" (97). Of course, "the prospective prize" here is salvation. Schlesinger is suggesting

that decision theory should be supplemented with a new principle. In our present case, it amounts to this: rationality requires you to perform the action that maximizes your probability of salvation. This clearly rules out the coin-tossing strategy, the die-tossing strategy, and all the other mixed strategies, since these have lower probabilities of your achieving salvation than outright wagering for God does. Sorensen 1994 objects to Schlesinger's new principle as being ad hoc. In any case, Pascal does not appeal to the principle in his argument. As it stands, the argument is apparently invalid.

The problem is that multiplying ∞ by any positive, finite probability again yields ∞. Let us call this property of ∞ *reflexivity under multiplication* (by such a probability). Such reflexivity is at once the strength of the Wager (for then Pascal does not need to say anything more about your probability of God's existence), and its weakness (for then all the various mixed strategies get maximal expectation also). One could try to fix the weakness, while saving as much one can of the strength. This would involve finding a utility for salvation that is not reflexive under multiplication, yet which is still sufficiently large to swamp your probability, whatever it is, in the expectation calculation.

For instance, if the utility of salvation were enormous, but finite, then the mixed strategies would yield lower expectation than outright wagering for God (multiplying that utility by 1/2, 1/6, etc. makes a difference). And the utility could be made enormous enough to offset any actual person's probability assignment, however small (provided it is positive and finite), so that the expectation of outright belief is maximal for everybody. Or suppose that the utility of salvation were an infinite number that is not reflexive under multiplication. Consider, for example, the infinite numbers of non-standard analysis (see Robinson 1966, Nelson 1987), or the surreal infinite numbers of Conway 1976. Multiplication of such a utility by a positive, finite probability (less than 1) yields another, smaller infinite number. So the expectation of wagering for God again exceeds that of wagering against God, whatever your probability is (provided it is positive and finite), and also that of each mixed strategy. See Hájek 2000a for further devices along these lines.

These proposals appear to yield valid arguments for wagering for God, where Pascal's argument was invalid. The trouble is that they do not seem adequately to capture Pascal's reasoning. He writes: "Unity added to infinity adds nothing to it". Let us call this property of infinity *reflexivity under addition*. We can see why Pascal would want the utility of salvation to be reflexive under addition: salvation is supposed to be the best possible thing. But if that utility is finite, or non-standard infinite, or surreal infinite, then adding one to it does make a difference. What is wanted, then, is the seemingly impossible: a representation of the reward of salvation that is reflexive under addition (so that it cannot be bettered), but not reflexive under multiplication by positive, finite probabilities (so that the mixed strategies can be distinguished in expectation from outright belief).

The St. Petersburg Paradox

The St. Petersburg game is played by flipping a fair coin until it comes up tails, and the total number of flips, n, determines the prize, which equals $\$2^n$. Thus if the coin comes up tails the first time, the prize is $\$2^1 = \$2$, and the game ends. If the coin comes up heads the first time, it is flipped again. If it comes up tails the second time, the prize is $\$2^2$, = \$4, and the game ends. If it comes up heads the second time, it is flipped again. And so on. There are an infinite number of possible ‘consequences’ (runs of heads followed by one tail) possible. The probability of a consequence of n flips (‘P(n)’) is 1 divided by 2^n, and the ‘expected payoff’ of each consequence is the prize times its probability. The following table lists these figures for the consequences where n = 1 ... 10:

n	P(n)	Prize	Expected payoff
1	1/2	\$2	\$1
2	1/4	\$4	\$1
3	1/8	\$8	\$1
4	1/16	\$16	\$1
5	1/32	\$32	\$1
6	1/64	\$64	\$1
7	1/128	\$128	\$1
8	1/256	\$256	\$1
9	1/512	\$512	\$1
10	1/1024	\$1024	\$1

The ‘expected value’ of the game is the sum of the expected payoffs of all the consequences. Since the expected payoff of each possible consequence is \$1, and there are an infinite number of them, this sum is an infinite number of dollars. A rational gambler would enter a game iff the price of entry was less than the expected value. In the St. Petersburg game, any finite price of entry is smaller than the expected value of the game. Thus, the rational gambler would play no matter how large the finite entry price was. But it seems obvious that some prices are too high for a rational agent to pay to play. Many commentators agree with Hacking's (1980) estimation that "few of us would pay even \$25 to enter such a game." If this is correct, then something has gone wrong with the standard decision-theory calculations of expected value above. This problem, discovered by the Swiss eighteenth-century mathematician Daniel Bernoulli (1738;

English trans. 1954) is the St. Petersburg paradox.

Decreasing Marginal Utility

Bernoulli responded to this problem with the observation that the calculations err by adding expected payoffs in dollars, whereas what should be added are the expected utilities of each consequence. He proposed the widely-accepted principle that (roughly speaking) money has a decreasing marginal utility, and suggested that a realistic measure of the utility of money might be given by the logarithm of the money amount. Here are the first few lines in the table for this gamble if utiles = log($):

n	P(n)	Prize	Utiles	Expected Utility
1	1/2	$2	0.301	0.1505
2	1/4	$4	0.602	0.1505
3	1/8	$8	0.903	0.1129
4	1/16	$16	1.204	0.0753
5	1/32	$32	1.505	0.0470
6	1/64	$64	1.806	0.0282
7	1/128	$128	2.107	0.0165
8	1/256	$256	2.408	0.0094
9	1/512	$512	2.709	0.0053
10	1/1024	$1024	3.010	0.0029

The sum of expected utilities is not infinite: it reaches a limit of about 0.60206 utiles (worth $4.00). The rational gambler, then, would pay any sum less than $4.00 to play.

This response to the paradox is, however, unsatisfactory. Let us agree that money has a decreasing marginal utility, and accept (for the purposes of argument) that a reasonable calculation of the utility of any dollar amount takes the logarithm of the amount in dollars. The St. Petersburg game as proposed, then, presents no paradox, but it is easy to construct another St. Petersburg game which is paradoxical, merely by altering the dollar prizes. Suppose, for example, that instead of paying $\$2^n$ for a run of n, the prize were \$10 to the power 2^n. Here is the table for this game:

n	P(n)	Prize	Utiles of Prize	Expected utility
1	1/2	$\$10^2$	2	1
2	1/4	$\$10^4$	4	1
3	1/8	$\$10^8$	8	1
4	1/16	$\$10^{16}$	16	1
5	1/32	$\$10^{32}$	32	1
6	1/64	$\$10^{64}$	64	1
7	1/128	$\$10^{128}$	128	1
8	1/256	$\$10^{256}$	256	1
9	1/512	$\$10^{512}$	512	1
10	1/1024	$\$10^{1024}$	1024	1

This version contains much larger prizes than the original version, and one would presumably be willing to pay more to play this version than the original. But the expected value of this game - the sum of the infinite series of numbers in the last column - is infinite, and the paradox returns.

Of course, it is not clear how in fact dollar values relate to utility, but we can imagine a generalized paradoxical St. Petersburg game (suggested by Paul Weirich, 1984, following Menger, 1967) which offers prizes in utiles at the rate of 2^n *utiles* for a run of n, however that number of utiles is to be translated into dollars or other goods. This game would have infinite expected value, and the rational gambler should pay any amount, however large, to play. For simplicity, we shall ignore the generalized version of the game, and continue to discuss it in terms of the original dollar prizes, recognizing, however, that the diminishing marginal utility of dollars may make some revision of the prizes necessary to produce the paradoxical result.

Risk-Aversion

Consider the following argument. The St. Petersburg game offers the possibility of huge prizes. A run of forty would, for example, pay a whopping \$1.1 trillion. Of course, this prize happens rarely: only once in about 1.1 trillion times. Half the time, the game pays only \$2, and you're 75% likely to wind up with a

payment of $4 or less. Your chances of getting more than the entry price of $25 which Hacking suggests are less than one in 25. Very low payments are very probable, and very high ones very rare. It's a foolish risk to invest more than $25 to play.

This sort of reasoning is appealing, and may very well account for intuitions that agree with Hacking's. Many of us are risk-averse, and unwilling to gamble for a very small chance of a very large prize, because the chance is so small. Weirich claims that this sort of consideration in fact solves the St. Petersburg paradox. He offers a complicated way (which we need not go into here) of including a risk-aversion factor in our rational calculations, with the result that there is a finite upper limit to the rational entrance fee for the game.

But there are objections to this approach. For one thing, a factor for risk-aversion is not a generally applicable consideration in making rational decisions, because some people are not risk averse. In fact, some people may enjoy risk. What should we make, for example, of those people who routinely play state lotteries, or who gamble at pure games of chance in casinos? (In these games, the entry fee is greater than the expected utility.) It's possible to dismiss such behaviour as merely irrational, but sometimes these players offer the explanation that they enjoy the excitement of risk. In any case, it's not at all clear that risk-aversion can explain why the St. Petersburg game would be widely intuited to have a fairly small maximum rational entry fee, while so many people at the same time are not averse to the huge risk entailed by the very small expected probability of large prizes in lotteries.

But for the purposes of argument, let's assume that risk-aversion is what's responsible for the rational intuition that the appropriate entrance-fee for the St. Petersburg game is finite and small. But this will not make the paradox go away, for we can again adjust the prizes to take account of this risk-aversion.

Suppose you don't like to gamble, and wouldn't risk an entry fee in a game that offers a small possibility of a large prize, even when the odds were in your favour. For example, imagine that you were offered a lottery ticket costing $1, which gave you a one-in-ten chance at a prize of $20. Playing costs you utility, because you hate risk. But presumably, we could compensate you for this utility-loss by making the prize even bigger. Maybe you would invest $1 for a one-in-ten chance at making $100. If not, how about $1000? It appears that there is some prize large enough to compensate you for your risk aversion.

Now let's imagine that you consider the St. Petersburg game, and suppose that you're willing to pay an entrance fee of only $20 to play. The reason you're not willing to go higher is your risk-aversion. We can imagine that the increasing risk of large payments subtracts from their utility, and the result is that the last column contains numbers that decrease as probabilities shrink, and the sum of the last column reaches a limit - perhaps $25. But now, the game can be reformulated to repay you for the risk inherent in each outcome, by correspondingly increasing the prizes. For example, suppose we square each dollar-prize in compensation for the increasing risk - the lower probability - of the larger prizes. If this doesn't provide sufficient compensation for your risk-aversion, then we can make the prizes even higher. In any case, there seems to be some prize scheme huge enough to compensate you for your risk-aversion - one which makes the dollar utility of each prize minus its risk-factor equal 1 utile. A game with these larger prizes is again paradoxical.

But Weirich argues that offering increased prizes cannot sufficiently compensate for risk-aversion in such a way as to make the sum of the series unlimited. He appears to suggest that increasing the prize for an outcome may increase one's cost in terms of dread of risk. In the lottery example, then, increasing the prize to $1000 would correspondingly increase the risk for you, so you still wouldn't bet. No matter how high a prize you are offered, you still are unwilling to buy the ticket for $1, because the higher prizes raise the risk for you. Putting it ‘picturesquely,’ he says, ‘there is some number of birds in hand worth more than any number of birds in the bush.’

But one might doubt that risk-aversion works this way - or, anyway, that this sort of risk-aversion can be justified as rational. It's highly implausible to claim that an increase in prize-size increases the risk of a game. In the lottery example, the only sort of risk-aversion that would make one refuse to play no matter how high the prize is pathological, not rational. There must be some prize which is so valuable to any rational but risk-averse person that the person would see it as compensating him for the risk of $1, (where that dollar has the usual small utility). If someone prefers $1 worth of birds in hand to any value of birds in the bush, then that person needs psychiatric help; this is not a rational decision strategy.

One might argue, however, for a risk-aversion factor such that increase in prizes makes certain games more attractive, but never attractive enough to override the risk factor. The most obvious way to take risk-aversion into consideration in calculating the utility of a game would be to add the negative utility of its risk to the positive utility of each prize, as if its risk were a negative aspect of the prize. On this way of calculating, it is always possible to compensate for risk by increasing the utility of the payoff. But Weirich's proposal appears to make risk a function of the whole gamble and of one's current utility level, in such a way that no addition to the prizes can make a game desirable to a risk-averse agent. This might seem implausible: if one's risk-aversion to a game is finite, and does not increase merely because of increase in payoffs, and if the utility of the prizes can be increased without limit, it would seem that some prize-increase can always compensate for the risk-aversion, however it is reasonably calculated. But if prize-increase, while increasing the expected utility (ignoring the risk-factor) of the whole game, nevertheless cannot make it sufficient to overcome the finite risk-aversion, then something else (such as the diminishing marginal utility of prizes, or an upper limit on their utility) is operating. These possibilities are discussed elsewhere in this article.

But the St. Petersburg game is supposed to justify even an enormously high entry price, so the lottery example is not precisely germane. Let's consider examples with a high entry price, for example, your entire life-savings. Would it be rational always to refuse to risk this, no matter what the gamble is? It doesn't seem so. When you deposit your life-savings in a solid bank for a year, you are in fact accepting a gamble. There's a very high probability of the consequence that at the end of the year, you can get your savings back with interest, but there's also an extremely low probability that the bank and the deposit insurance will both collapse, and you'll be wiped out. Someone who refused to run this very tiny risk no matter how high the interest and how low the probability of disaster is clearly irrational. Everyone who crosses a street is, in effect, gambling his life, because crossing a street increases, to a small extent, the risk of being run down and killed. But to refuse to cross any street on these grounds is irrational. This sort of risk-aversion, when generally applied, would paralyze anyone. It is central to rationality that one take

account of the actual risks, and run suitably small ones.

The counter argument we have been considering is that risk-aversion is irrational when it refuses to gamble a small entry-price for no matter how high a prize, or when it refuses to gamble a large entry-price for no matter how high a probability of prize. But this does not answer all St. Petersburg objections, for here we imagine a gamble with a large entry-price and a small probability of large prizes. The most compelling examples of the rational unacceptability of risk no matter how high the prize, are the ones in which the entry price is high and the prize improbable. Imagine, for example, that you are risk averse, and are offered a gamble in which the entry price is your life-savings of (say) $100,000, and the chances of the prize are one-in-a-million. It seems rational to refuse, no matter how huge the prize. The reason for this is worth considering.

Classical decision theory says that, for this gamble to be rational, the prize must be enormous: in the imagined case, at least one million times the value of your life-savings - more than a hundred billion dollars. Compensating you for your risk-aversion by increasing the size of this prize makes it even larger - two hundred billion? a trillion? - so huge that our intuitions are inadequate to appreciate such a value. What is worth much more than a million times your life-savings? You don't know. Your intuitions boggle when considering this gamble. The diminishing marginal utility of money and of ordinary goods operates here as well. You might suppose that nothing would give you that much utility. But the facts that the world happens not to contain such huge utilities, or that one's intuitions get unreliable when considering them, are not difficulties with classical decision theory per se. More will be said about this below, when the argument will be proposed that these these sorts of practical considerations don't show that there's something wrong with classical decision theory.

Let us, then, increase the prizes in the St. Petersburg game to compensate a rational potential player for his risk-aversion, and the game once again has infinite expected value for that person.

An Upper Bound on Utility

The two reformulations of the game proposed so far share the feature that the dollar values of the prizes are increased as compensation (in the first case, for the diminishing marginal value of money, and, in the second case, for their improbability and risk-aversion). In both cases, it is assumed that the utility of each outcome can be increased without limit; but perhaps this assumption is incorrect, and there is an upper limit on the utility of the prizes. Then the sum of the series will reach a limit. In his classical treatment of the problem, Menger argues that the assumption that there is an upper limit to utility is the only way that the paradox can be resolved. Assume, for example, that utility = dollar value, except with an upper limit of 100 utiles. The chart for the game then looks like this:

n	P(n)	Prize	Utiles of Prize	Expected utility
1	1/2	$2	2	1
2	1/4	$4	4	1

3	1/8	$8	8	1
4	1/16	$16	16	1
5	1/32	$32	32	1
6	1/64	$64	64	1
7	1/128	$128	100	0.78
8	1/256	$256	100	0.391
9	1/512	$512	100	0.195
10	1/1064	$1064	100	0.098

The sum of the infinite series in the right-hand column reaches a limit of about 7.56, and the rational entry price is anything under $7.56.

The assumption that maximum utility is reached by any dollar-prize over $100 is implausible because it means that the value of $100, $1000, and $1,000,000 are all the same - the maximum. A more plausible point for maximum utility of dollars is much higher. Setting it at 16,000,000 makes the maximum rational entry price of the game close to $25, which is Hacking's guess at what our intuitions would accept.

Some people think that it is reasonable to set an upper limit on utility. Russell Hardin (1982), for example, calls this assumption "compelling in its own right." William Gustason (1994) suggests that one restrict the expected value concept by stipulating that values of any consequence have an upper bound. Richard Jeffrey (1983) agrees.

But the idea of an upper limit on utility might not be seen to be compelling in its own right. Note that this idea must be distinguished from the diminishing marginal value of money. Perhaps you find it reasonable to think that, once one had (say) $16,000,000 in the bank, you'd be able to buy anything you could possibly want; but this is not to say that that sum of money provides the maximum permissible utility. We can readily imagine someone with that amount of money - or any amount of money - still short of utility, due to lack of certain goods that money can't buy. What the idea of an upper limit on utility means is that there is some amount of utility which is so high that no additional utility is possible - that nothing additional adds any value at all. Imagine someone with all the wealth he could use: still he might have unfulfilled desires, for example, that his friends and relations be as fortunate as he. If this desire were fulfilled, then he might still desire that strangers be as fortunate; and that there be more people on earth than there currently were, to share his happiness, and more populated planets full of happy people. How many more? Why, the more the better - indefinitely more. If there is an upper limit on utility, then there is some finite amount of utility which is maximally good, an amount for which one would rationally trade anything else. It doesn't appear plausible to think that there is any such amount.

One might imagine that some people have an upper limit on the utility they can enjoy - people who have a finite number of desires, and whose desires can each be completely satisfied by some finite state. For these people, the utility of prizes does not increase without limit, and the St. Petersburg game has some

finite expected utility. Do such people exist? This is an empirical question. In any case, there surely are some people with some ‘the-more-the-better’ desires, and the theory of rational choice ought not to be restricted by the empirical and doubtful propositions that there aren't any, and that value cannot increase without limit. And these propositions are surely insufficiently well-founded to invoke to solve the St. Petersburg paradox.

Gustason says that "the upshot of the paradox is that if there is such a thing as an infinite value, then acts and consequences that involve it are beyond the scope of the expected value concept." Jeffrey states that the evaluation theory we are applying here has "from its inception...been closely tied to the notion that desirabilities are ... bounded." But the fact that the theory wasn't designed with such a result in mind is not a very good reason to try to resist its application in this case. The main reason both authors give for excluding unbounded-desirability games is that otherwise the St. Petersburg game has infinite expected utility. But this ad-hoc rationale is not compelling unless one can't bear this result. The acceptability of this result will be considered later.

Hardin offers the opinion that whether utility is bounded "is more a factual than a logical issue," and that its invocation to resolve the St. Petersburg paradox "is to grant that the paradox is not an antinomy." He may mean that the difficulty posed by the game is a result of a factual assumption that utility is unbounded (and not merely by its logical features), and can be removed by rejecting that assumption. But if one finds no no difficulty posed by the game, one is not tempted to reject the assumption.

Finitely Many Consequences

Gustason suggests that, in order to avoid the St. Petersburg problem, one has the choice between two restrictions on the expected value concept:

> (a) Each act has only finitely many consequences, or
>
> (b) Values must be ‘bounded,’ i.e., there are numbers n and m such that no value to be assigned a consequence exceeds n or is less than m.

He points out that imposing either restriction will suffice to rule out the St. Petersburg result. If one resists imposing restriction (b), in this case, by setting an upper bound to the value of consequences, perhaps restriction (a) might be found plausible.

One way to impose restriction (a) is merely to insist that the St. Petersburg game fails to meet it, so its value, and fair entrance price, cannot be calculated using standard expected value theory. How then, if at all, can it be calculated? Where does the intuition that $25 is too much to pay come from (if anywhere)? How (if at all) can it be justified?

Another way is to assume that the way the game will take place is not exactly as described, and that there are some possible very long strings that would never be carried out - i.e., that there is only a finite number

of prizes to be considered when calculating the expected value of the game. Presumably, this would be applied by setting some upper limit L to the number of flips which would be considered; after a run of L heads in a row, the game would be terminated and payment made for the run so far, despite the fact that tails hadn't yet come up. If L were set at 25, then the game would have an expected value of $25, and that would be the maximum entry price which a rational agent would pay to play (as in Hacking's intuition). Do we, perhaps unconsciously, assume that any run of 25 heads would be truncated, and paid off, at that point?

Many authors have pointed out that, practically speaking, there must be some point at which a run of heads would be truncated without a final tail. For one thing, the patience of the participants of the game would have to end somewhere. If you think that this sets too narrow a limit L, consider the considerably higher limit set by the life-spans of the participants, or the survival of the human race; or the limit imposed by the future time when the sun explodes, vaporizing the earth. Any of these limits produces a finite expected value for the game, but sets an L which is higher than 25; what, then, explains Hacking's $25 intuition?

Another fact that would set a limit on L is the finitude of the bankroll necessary to fund the game. Any casino that offers the game must be prepared to truncate any run that, were it to continue, would cost them more than the total funds they have available for prizes. A run of 25 would require a prize of a mere $33,554,432, possibly within the reach of a larger casino. A run of 40 would require a prize of about 1.1 trillion dollars.

Other facts make an upper limit L plausible, such as the limit on the amount of money available in the world. Perhaps all these financial limits can be overridden if we conceive of the game's being offered by a state capable of printing all the money it wanted to. This state could pay any prize whatever; but printing up and handing out a huge amount of cash would create havoc with any economy, so no rational state would.

Hardin claims that "the slightest bit of realism is sufficient to do in the St. Petersburg Paradox." But is the slightest bit of realism a justifiable consideration? The fact of which we are sure, that some upper limit on L, and thus a finite number of possible consequences of the game, would certainly be imposed, does not really solve the St. Petersburg problem because it does not show that the expected value of the game as described is not infinite. After all, any game with a limit L is not the game we have been talking about. Our question was about the St. Petersburg game, not about its relative.

One might argue: we are considering the St. Petersburg game, but under realistic conditions. Realistically, the game would be truncated, whether this is mentioned in its rules or not. Thus there is a finite and realistic price for entry. But if this is the case, why isn't the game offered, with an entry price somewhat above this (to produce a profit in the long run) by casinos (who after all, are quite realistic)?

Do these realistic considerations show that the genuine St. Petersburg game - exactly as originally described - can never be encountered in real life? Jeffrey says: "Put briefly and crudely, our rebuttal of the

St. Petersburg paradox consists in the remark that anyone who offers to let the agent play the St. Petersburg game is a liar, for he is pretending to have an indefinitely large bank."

It can be quibbled that Jeffrey is not exactly right: that someone can offer a game even though he is aware that there's a possibility that this offer involves the possibility of requiring consequences he cannot fulfill. Compare my offer to drive you to the airport tomorrow. I realise that there's a small possibility my car will break down between now and then, and thus that I'm making an offer I might not be able to fulfill. But the conclusion is not that I'm not really offering what I appear to be. If someone invites you to play St. Petersburg, we can't conclude that he's in fact not offering the St. Petersburg game, that he's really offering some other game.

Real casinos right now play games that offer the extremely remote possibility of continuing too long for anyone to complete, or of prizes too large to be managed. Casinos can go ahead and play these games anyway, confident that the risk of running into an impossible situation is very very small. They need not lose any sleep worrying about incurring a debt they can't manage. They live, and prosper, on probabilities, not certainties.

If these considerations are persuasive, then what Jeffry gives then is not a rebuttal of the paradox. In effect, he accepts the fact that the game offers the possibility of indefinitely large payoffs. The reason the game is not offered by casinos is that they realise that sooner or later (probably much later) the game will bankrupt them. This is correct reasoning - but it is done using the ordinary, general theory of choice. When casinos reason about the game, they do not decide that, since ordinary theory shows that the game has infinite value, ordinary theory should be restricted to exclude its consideration.

There are other reasons why we should not restrict theory to exclude consideration of the game. This ruling, in order to be theoretically acceptable, ought not merely rule out the St. Petersburg game in particular, ad hoc; it ought to be general in scope. And if it is, it will also rule out perfectly acceptable calculations. Michael Resnik (1987) notes that utility theory "is easily extended to cover infinite lotteries, and it must be in order to handle more advanced problems in statistical decision theory" but he gives no examples.

Imagine a life insurance policy bought for a child at its birth, which pays to the child's estate, when it eventually dies, $1000 for each birthday the child has passed, without limit. What price should an insurance company charge for this policy? (For simplicity, we shall ignore possible effects of inflation, and profits from investing the entry price.) Standard empirically-based mortality charts give the chances of living another year at various ages. Of course, they don't give the chances of surviving another year at age 140, because there's no empirical evidence available for this; but a reasonable function to extend the mortality curve indefinitely beyond what's provided by available empirical evidence can be produced; this curve asymptotically approaches zero. On this basis, ordinary mathematical techniques can give the expected value of the policy. But note that it promises to pay off without limit. If we think that, for each age, there is a (large or small) probability of living another year, then there are an indefinitely large number of consequences to be considered when doing this calculation, but mathematics can calculate the limit of this infinite series; and (ignoring other factors) an insurance company will make a profit, in the

long run, buy charging anything above this amount. There's no problem in calculating its expected value.

This insurance policy (call it Policy 1) offers an indefinite number of outcomes; but consider a different one (call it Policy 2) which would truncate the series at age 140, and offer only 140 outcomes. The probability of reaching age 140 is so tiny that the difference in expected value between the two policies is negligible, a tiny fraction of 1 cent. If you don't like infinite lotteries, you might claim that Policy 1 is ill-formed, and suggest substitution of Policy 2, pointing out that the expected value of this one is, for all practical purposes, equal to that of Policy 1. But note that your judgment that the two are virtually identical in expected value depends on your having calculated the expected value of Policy 1. So your statement presupposes that the expected value of Policy 1 is calculable, after all.

Infinite Value?

The St. Petersburg game is sometimes dismissed because it is has infinite expected value, which is thought not merely practically impossible, but theoretically objectionable - beyond the reach even of thought-experiment. But is it?

Imagine you were offered the following deal. For a price to be negotiated, you will be given permanent possession of a cash machine with the following unusual property: every time you punch in a dollar amount, that amount is extruded. This is not a withdrawal from your account; neither will you later be billed for it. You can do this as often as you care to. Now, how much would you offer to pay for this machine? Do you find it impossible to perform this thought-experiment, or to come up with an answer? Perhaps you don't, and your answer is: any price at all. Provided that you can defer payment for a suitable time after receiving the machine, you can collect whatever you need to pay for it from the machine itself.

Of course, there are practical considerations: how long would it take you to collect, say, a trillion dollars from the machine, if this were its price? Would you be worn out or dead by then? Any bank would be crazy to offer to sell you an infinite cash machine, and unfortunately I seem to have lost the address of the crazy bank which has made this offer. Anyway, there appears to be nothing wrong with this thought experiment: it imagines an action (buying the machine) with no upper limit on expected value. We easily ignore practical considerations when calculating the expected value (in this case, merely potential withdrawals minus purchase price), which is infinite.

Do your intuitions tell you to offer (say) $25 at most for this machine? I doubt that they do. But the only difference between this machine and a single-play St. Petersburg game is that this machine guarantees an indefinitely large number of payouts, while the game offers a one-time lottery from among an indefinitely large number of possible payouts, each with a certain probability. The only difference between them is the probability factor: the same difference that exists between a game which gives you a guaranteed prize of $5, and one which gives you half a chance of $10, and half a chance of $0. The expected value of both the St. Petersburg game and the infinite cash machine are both indefinitely large. You should offer any price at all for either. It appears, then, that the notion of infinite expected value is perfectly reasonable.

In a sense, the counter-intuitiveness of the St. Petersburg result is a special case of a general and familiar objection to classical decision theory. Someone might object that it would be perfectly rational for you to prefer a guaranteed prize of $5 to a gamble which offers half a chance of $10, and half a chance of $0, despite the theory's claim that they have equal value. If you intuit that an infinite cash machine has infinite expected value, but the St. Petersburg game does not, you're probably relying on this more general objection to classical theory. Arguments can be made that your preference of the guaranteed prize to the gamble is irrational; or attempts can be made to "fix" the theory to account for the rationality of this preference (for example, by allowing adjustments for risk-aversion.) However this more general "problem" with classical theory is dealt with, it is not a problem with St. Petersburg alone, and making ad-hoc fixes to theory to rule out St. Petersburg will not help in dealing with this more general problem.

Theory and Practicality

The St. Petersburg game is one of a large number of examples which have been brought against standard (unrestricted) Bayesian decision theory. Each example is supposed to be a counter-example to the theory because of one or both of these features: (1) the theory, in the application proposed by the example, yields a choice people really do not, or would not make; thus it is descriptively inadequate. (2) the theory, in the application proposed by the example, yields a choice people really ought not to make, or which a fully, ideally rational person, would not make; thus it is normatively inadequate.

If you see standard theory as normative, you can ignore objections of the first type. People are not always rational, and some people are rarely rational, and an adequate descriptive theory must take into account the various irrational ways people really do make decisions. It's no surprise that the classical rather a-prioristic theory fails to be descriptively adequate, and to criticize it on these grounds rather misses its normative point.

T he objections from standpoint (2) need to be taken more seriously; and we have been treating the responses to St. Petersburg as cases of this sort. Various sorts of "realistic" considerations have been adduced to show that the result the theory draws in the St. Petersburg game about what a rational agent should do is incorrect. It's concluded that the unrestricted theory must be wrong, and (sometimes) that it must be restricted to exclude consideration of the game as invented. We'll now consider the general plausibility of restricting the theory in these ways.

When considering the plausibility of restricting expected value calculations in various ways that would rule out the St. Petersburg calculation, Amos Nathan (1984) remarks, "it ought, however, to be remembered that important and less frivolous application of such games have nothing to do with gambling and lie in the physical world where practical limitations may assume quite a different dimension." Nathan doesn't mention any physical applications of analogous infinite value calculations. But it's nevertheless plausible to think that imposing restrictions on theory to rule out St. Petersburg bath water would throw out some valuable babies as well.

Any theoretical model is an idealization, leaving aside certain practicalities. "From the mathematical and

logical point of view," observes Resnick, "the St. Petersburg paradox is impeccable." But this is the point of view to be taken when evaluating a theory per se (though not the only point of view ever to be taken). By analogy, the aesthetic evaluation of a movie does not take into account the facts that the only local showing of the movie is far away, and that finding a baby sitter will be impossible at this late hour. If aesthetic theory tells you that the movie is wonderful, but other considerations show you that you shouldn't go, this isn't a defect in aesthetic theory. Similarly, the mathematical/logical theory for explaining ordinary casino games is not defective because it ignores practicalities such as a particular limit on a casino's bankroll, or on participants' patience.

There are all sorts of practical considerations which must be considered in making a real gambling decision. For example, in deciding whether to raise, see, fold, or cash in and go home, in a particular poker game, you must consider not only probability and expected value, but also the facts that it's 5 A.M. and you are cross-eyed from fatigue and drink; but it's not expected that classical decision theory has to deal with these.

The St. Petersburg game commits participants to doing what we know they will not. The casino may have to pay out more than it has. The player may have to flip a coin longer than physically possible. But this may not show a defect with choice theory. Classical unrestricted theory is still serving its purpose, which is modeling the abstract ideal rational agent. It tells us that no amount is too great to pay as a ideally rationally acceptable entrance fee, and this may be right. What it's reasonable for real agents, limited in time, patience, bankroll, and imaginative capacity to do, given the constraints of the real casino, the real economy, and the real earth, is another matter, one that the theoretical core of decision theory can be forgiven for not specifying. From this point of view, the St. Petersburg ‘paradox’ does not, after all, point out any defect with classical decision theory, and is not a paradox after all.

Friedrich Nietzsche

Friedrich Nietzsche was a German philosopher of the late 19th century who challenged the foundations of traditional morality and Christianity. He believed in life, creativity, health, and the realities of the world we live in, rather than those situated in a world beyond. Central to Nietzsche's philosophy is the idea of "life-affirmation," which involves an honest questioning of all doctrines which drain life's energies, however socially prevalent those views might be. Often referred to as one of the first "existentialist" philosophers, Nietzsche has inspired leading figures in all walks of cultural life, including dancers, poets, novelists, painters, psychologists, philosophers, sociologists and social revolutionaries.

Life: 1844-1900

In the small German town of Röcken bei Lützen, located in a rural farmland area southwest of Leipzig, Friedrich Wilhelm Nietzsche was born at approximately 10:00am on October 15, 1844. The date coincided with the 49th birthday of the Prussian King, Friedrich Wilhelm IV, after whom Nietzsche was named, and who had been responsible for Nietzsche's father's appointment as Röcken's town minister. Nietzsche's grandfathers were also Lutheran ministers, and his paternal grandfather, Friedrich August Ludwig Nietzsche, was further distinguished as a Protestant scholar, one of whose books (1796) affirmed the "everlasting survival of Christianity." When Nietzsche was 4 years old, his father, Karl Ludwig Nietzsche (1813-1849) died from a brain ailment, and the death of Nietzsche's two-year-old brother, Joseph, followed six months later. Having been living only yards away from Röcken's church in the

house reserved for the pastor and his family, the remaining Nietzsche family left their home soon after Karl Ludwig’s death. They moved to nearby Naumburg an der Saale, where Nietzsche (called "Fritz" by his family) lived for the next eight years with his mother, Franziska (1826-1897), his paternal grandmother, Erdmuthe, his father’s two sisters, Auguste and Rosalie, and his younger sister, Therese Elisabeth Alexandra (1846-1935).

From the ages of 14 to 19, Nietzsche attended a first-rate boarding school, Schulpforta, located not far from Naumburg, where he prepared for university studies. Here he met his lifelong acquaintance, Paul Deussen, who was confirmed at Nietzsche’s side in 1861, and who was to become an Orientalist, historian of philosophy, and in 1911, the founder of the Schopenhauer Society. During his summers in Naumburg, Nietzsche led a small music and literature club named "Germania," and became acquainted with Richard Wagner’s music through the club’s subscription to the *Zeitschrift für Musik.* The teenage Nietzsche also read the German romantic writings of Friedrich Hölderlin and Jean-Paul Richter, along with David Strauss’s controversial and demythologizing *Life of Jesus Critically Examined* (*Das Leben Jesu kritisch bearbeitet*, 1848).

After graduating from Schulpforta, Nietzsche entered the University of Bonn in 1864 as a theology and philology student, but his interests gravitated more exclusively towards philology -- a discipline which then centered upon the interpretation of classical and biblical texts. As a philology student, Nietzsche attended lectures by Otto Jahn (1813-1869) and Friedrich Wilhelm Ritschl (1806-1876). Jahn was a biographer of Mozart who had studied at the University of Berlin under Karl Lachmann (1793-1851) -- a philologist known both for his studies of the Roman philosopher Lucretius and for having developed the genealogical method in textual recension; Ritschl was a classics scholar whose work centered on the Roman comic poet Plautus (254-184 BC). Inspired by Ritschl, and following him to the University of Leipzig in 1865 -- an institution located closer to Nietzsche’s hometown of Naumburg -- Nietzsche quickly established his own academic reputation through his published essays on Aristotle, Theognis and Simonides. In Leipzig, he developed a close friendship with Erwin Rohde, a fellow philology student, with whom he would correspond extensively in later years. Momentous for Nietzsche in 1865 was his accidental discovery of Arthur Schopenhauer’s *The World as Will and Representation* (1818) in a local bookstore. He was then 21. Schopenhauer’s atheistic and turbulent vision of the world, in conjunction with his highest praise of music as an art form, captured Nietzsche’s imagination, and the extent to which the "cadaverous perfume" of Schopenhauer’s world-view continued to permeate Nietzsche’s mature thought is still a matter of scholarly debate. After discovering Schopenhauer, Nietzsche read F.A. Lange’s newly-published *History of Materialism and Critique of its Present Significance* (1866) -- a work which criticized materialist metaphysical theories from the standpoint of Kant’s critique of metaphysics in general, and attracted Nietzsche’s interest in its view that metaphysical speculation is an expression of poetic illusion.

In 1867, as he approached the age of 23, Nietzsche entered his required military service and was assigned to an equestrian field artillery regiment close to Naumburg, during which time he lived at home with his mother. While attempting to leap-mount into the saddle upon a particularly unruly horse, he suffered a serious chest injury and was put on sick leave after his chest wound refused to heal. He returned shortly thereafter to the University of Leipzig, and in November of 1868, met the composer Richard Wagner

(1813-1883) at the home of Hermann Brockhouse, an Orientalist who was married to Wagner's sister, Ottilie. Wagner and Nietzsche shared an enthusiasm for Schopenhauer, and Nietzsche -- who had been composing piano, choral and orchestral music since he was a teenager -- admired Wagner for his musical genius and magnetic personality. Wagner was exactly the age Nietzsche's father would have been, and Wagner had also attended the University of Leipzig many years before. The Nietzsche-Wagner relationship was quasi-familial, sometimes-stormy, and it affected Nietzsche deeply: twenty years later, he would still be assessing Wagner's cultural significance. During the months surrounding Nietzsche's initial meeting with Wagner, Ritschl strongly recommended Nietzsche for a position on the classical philology faculty at the University of Basel. The Swiss university offered Nietzsche the position, and he began teaching there in May, 1869, at the extraordinary age of 24.

At Basel, Nietzsche's satisfaction with his life among his philology colleagues was limited, and he established closer intellectual ties to the historians Franz Overbeck and Jacob Burkhardt, whose lectures he attended. Nietzsche also cultivated his friendship with Wagner and visited him often at his Swiss home in Tribschen, a small town near Lucerne. Never in outstanding health, further complications arose from Nietzsche's August-October 1870 service as a hospital attendant during the Franco-Prussian War (1870-71). He witnessed the traumatic effects of battle, took close care of wounded soldiers, contracted diphtheria and dysentery, and subsequently experienced a painful variety of health difficulties for the rest of his life.

Nietzsche's enthusiasm for Schopenhauer, his studies in classical philology, his inspiration from Wagner, his reading of Lange, and his frustration with the contemporary German culture, coalesced in his first book -- *The Birth of Tragedy* (1872) -- which was published when he was 28. Wagner showered the book with unqualified praise, but a biting critical reaction by the young and promising philologist, Ulrich von Wilamowitz-Möllendorff (1848-1931), dampened the book's reception among scholars.

As he continued his residence in Switzerland between 1872 and 1879, Nietzsche often visited Wagner at his new (1872) home in Bayreuth, Germany. In 1873, Nietzsche met Paul Rée, who, while living in close company with Nietzsche, would write *On the Origin of Moral Feelings* (1877). In 1876, at age 32, Nietzsche made an unsuccessful marriage proposal to a Dutch piano student in Geneva named Mathilde Trampedach. During this time, Nietzsche completed a series of four studies on contemporary German culture -- the *Unfashionable Observations* (1873-76) -- which focussed, respectively, upon the historian of religion and culture critic, David Strauss, issues concerning the social value of historiography, and Arthur Schopenhauer and Richard Wagner as inspirations for new cultural standards. Near the end of his university career, Nietzsche completed *Human, All-Too-Human* (1878) -- a book which marked a turning point in his philosophical style, and which signalled the end of his friendship with Wagner, who came under attack in Nietzsche's thinly-disguised characterization of "the artist." Despite the unflattering review of *The Birth of Tragedy,* Nietzsche remained respected in his professorial position in Basel, but his ailing health, which led to migraine headaches, eyesight problems and vomiting, necessitated his resignation from the university in June, 1879.

From 1880 until his collapse in January 1889, Nietzsche led a wandering, gypsy-like existence as a "stateless" person (having given up his German citizenship, and not having acquired Swiss citizenship),

circling almost annually between his mother's house in Naumburg and various French, Swiss, German and Italian cities. His travels took him through the Mediterranean seaside city of Nice (during the winters), the Swiss alpine village of Sils-Maria (during the summers), Leipzig (where he had attended university), Turin, Genoa, Recoaro, Messina, Rapallo, Florence, Venice, and Rome, never residing in any place longer than several months at a time. On a visit to Rome in 1882, Nietzsche, now at age thirty-seven, met Lou Salomé, a twenty-one-year-old Russian woman who was studying philosophy and theology in Zurich. He soon fell in love with her, and offered his hand in marriage. She declined, and the future of Nietzsche's friendship with her and Paul Rée appears to have suffered as a consequence. In the years to follow, Salomé would become an associate of Sigmund Freud, and would write with psychological insight of her association with Nietzsche. These nomadic years were the occasion of Nietzsche's main works, among which are *Daybreak* (1881), *The Gay Science* (1882), *Thus Spoke Zarathustra* (1883-85), *Beyond Good and Evil* (1886), and *On the Genealogy of Morals* (1887). Nietzsche's final active year, 1888, saw the completion of *The Case of Wagner* (May-August 1888), *Twilight of the Idols* (August-September 1888), *The Antichrist* (September 1888), *Ecce Homo* (October-November 1888) and *Nietzsche Contra Wagner* (December 1888).

On the morning of January 3, 1889, while in Turin, Nietzsche experienced a mental breakdown which left him an invalid for the rest of his life. Upon witnessing a horse being whipped by a coachman at the Piazza Carlo Alberto, Nietzsche threw his arms around the horse's neck and collapsed, never to return to full sanity. Some argue that Nietzsche was afflicted with a syphilitic infection (this was the original diagnosis of the doctors in Basel and Jena) contracted either while he was a student or while he was serving as a hospital attendant during the Franco-Prussian War; some claim that Nietzsche's use of chloral hydrate, a drug which he had been using as a sedative, deteriorated his already-weakened nervous system; some speculate that Nietzsche's collapse was due to a brain disease he inherited from his father; some maintain that a mental illness gradually drove him insane. The exact cause of Nietzsche's incapacitation still remains unclear. That Nietzsche had an extraordinarily sensitive nervous constitution and took an assortment of medications is well-documented as a more general fact.

During his creative years, Nietzsche struggled to bring his writings into print and never doubted that his books would have a lasting cultural effect. He did not live long enough to experience his world-historical influence, but he had a brief glimpse of his growing intellectual importance in discovering that he was the subject of 1888 lectures given by Georg Brandes (Georg Morris Cohen) at the University of Copenhagen, with whom he corresponded. Nietzsche's collapse, however, followed soon thereafter. After a brief hospitalization in Basel, he spent 1889 in a sanatorium in Jena at the Binswanger Clinic, and in March 1890 his mother took him back home to Naumburg, where he lived under her care for the next seven years. After his mother's death in 1897, his sister Elisabeth -- having previously returned home from Paraguay, where she had been working with her husband Bernhard Förster to establish an Aryan, anti-Semitic German colony called "New Germany" ("Nueva Germania") -- assumed responsibility for Nietzsche's welfare. In an effort to promote her brother's philosophy, she rented a large house on a hill in Weimar, called the "Villa Silberblick," and moved both Nietzsche and his collected manuscripts to the residence. This became the new home of the Nietzsche Archives (which was previously located at the family home in Naumburg), where Elisabeth received visitors who wanted to observe the now-incapacitated philosopher. On August 25, 1900, Nietzsche died in the villa as he approached his 56th

year, apparently of pneumonia in combination with a stroke. His body was then transported to the family gravesite directly beside the church in Röcken bei Lützen, where his mother and sister now also rest.

Early Writings: 1872-1876

Nietzsche's first book was published in 1872: *The Birth of Tragedy, Out of the Spirit of Music* (*Die Geburt der Tragödie aus dem Geiste der Musik*). It was reissued in 1886 with the title *The Birth of Tragedy, Or: Hellenism and Pessimism* (*Die Geburt der Tragödie, Oder: Griechentum und Pessimismus*), and contained a prefatory essay -- "An Attempt at Self-Criticism" -- which expressed Nietzsche's own critical reflections on his earlier work. *The Birth of Tragedy* set forth an alternative conception to the late 18th/early 19th century understanding of Greek culture -- a conception largely inspired by Johann Winckelmann's *History of Ancient Art* (1764) -- which hailed ancient Greece as the epitome of noble simplicity, calm grandeur, clear blue skies, and rational serenity. Nietzsche, having by this time absorbed the German romanticist, and specifically Schopenhauerian, view that non-rational forces reside at the foundation of all creativity and of reality itself, identified a strongly instinctual, wild, amoral, "Dionysian" energy within pre-Socratic Greek culture as an essentially creative and healthy force. Surveying the history of Western culture since the time of the Greeks, Nietzsche lamented over how this "Dionysian," creative energy had been submerged and weakened as it became overshadowed by the "Apollonian" forces of logical order and stiff sobriety. He concluded that European culture since the time of Socrates had remained one-sidedly Apollonian and relatively unhealthy. As a means towards cultural rebirth, Nietzsche advocated the resurrection and fuller release of Dionysian artistic energies -- those which he associated with primordial creativity, joy in existence and ultimate truth. The seeds of this rebirth Nietzsche perceived in the contemporary German music of his time, and the concluding part of *The Birth of Tragedy,* in effect, adulates the German artistic spirit as the potential savior of European culture.

Some scholars regard Nietzsche's 1873 unpublished essay, "On Truth and Lies in an Nonmoral Sense" ("*Über Wahrheit und Lüge im außermoralischen Sinn*") as a keystone in his thought. In this essay, Nietzsche rejects the idea of universal constants, and claims that what we call "truth" is only "a mobile army of metaphors, metonyms, and anthropomorphisms." His view at this time is that arbitrariness completely prevails within human experience: concepts originate via the very artistic transference of nerve stimuli into images; "truth" is nothing more than the invention of fixed conventions for merely practical purposes, especially those of repose, security and consistency. Viewing human existence from a great distance, Nietzsche further notes that there was an eternity before human beings came into existence, and believes that after humanity eventually dies out, nothing significant will have changed in the great scheme of things.

Between 1873 and 1876, Nietzsche wrote the *Unfashionable Observations* (*Unzeitgemässe Betrachtungen*). These are four (of a projected, but never completed, thirteen) studies concerned with the quality of European, and especially German, culture during Nietzsche's time. They are unfashionable and nonconformist (or "untimely," or "unmodern") insofar as Nietzsche regarded his standpoint as culture-critic to be in tension with the self-congratulatory spirit of the times. The four studies were: *David*

Strauss, the Confessor and the Writer (*David Strauss, der Bekenner und der Schriftsteller,* 1873); *On the Uses and Disadvantages of History for Life* (*Vom Nutzen und Nachteil der Historie für das Leben*, 1874); *Schopenhauer as Educator* (*Schopenhauer als Erzieher,* 1874); *Richard Wagner in Bayreuth* (1876). The first of these attacked David Strauss, whose popular six-edition book, *The Old and the New Faith: A Confession* (1871) encapsulated for Nietzsche the general cultural atmosphere in Germany. Responding to Strauss's advocacy of a "new faith" grounded upon a scientifically-determined universal mechanism -- one, however, lubricated by the optimistic, "soothing oil" of historical progress -- Nietzsche unmercifully attacked Strauss's view as a vulgar and dismal sign of cultural degeneracy. The second "untimely meditation" surveyed alternative ways to write history, and discussed how these ways could contribute to a society's health. Here Nietzsche claimed that the principle of "life" is a more pressing and higher concern than that of "knowledge," and that the quest for knowledge should serve the interests of life. The third and fourth studies -- on Schopenhauer and Wagner, respectively -- addressed how these two thinkers, as paradigms of philosophic and artistic genius, held the potential to inspire a stronger, healthier and livelier German culture.

Middle-Period Writings: 1878-1882

In 1878, Nietzsche completed *Human, All-Too-Human,* supplementing this with a second part in 1879, *Mixed Opinions and Maxims* (*Vermischte Meinungen und Sprüche*), and a third part in 1880, *The Wanderer and his Shadow* (*Der Wanderer und sein Schatten*). The three parts were published together in 1886 as *Human All-Too-Human, A Book for Free Spirits* (*Menschliches, Allzumenschliches, Ein Buch für freie Geister*). Reluctant to construct a philosophical "system," and sensitive to the importance of style in philosophic writing, Nietzsche composed these works as a series of several hundred aphorisms whose typical length ranges from a line or two to a page or two. Here, he often reflects upon cultural and psychological phenomena in reference to individuals's organic and physiological constitutions. The idea of power (for which he would later become known) sporadically appears as an explanatory principle, but Nietzsche tends at this time to invoke hedonistic considerations of pleasure and pain in his explanations of cultural and psychological phenomena.

In *Daybreak, Reflections on Moral Prejudices* (*Morgenröte. Gedanken über die moralischen Vorurteile*, 1881), Nietzsche continued writing in his aphoristic style, but began accentuating the importance of the "feeling of power," as opposed to pleasure, in his understanding of human, and especially of so-called "moral" behavior. In this respect, *Daybreak* contains the seeds of Nietzsche's doctrine of the "will to power" -- a doctrine which would appear explicitly for the first time two years later in *Thus Spoke Zarathustra* (1883-85). *Daybreak* is also one of Nietzsche's clearest, intellectually calmest, and most intimate, volumes, providing many social-psychological insights, in conjunction with some of his first sustained critical reflections on the cultural relativity at the basis of Christian moral evaluations.

In a more well-known aphoristic work, *The Gay Science* (*Die fröhliche Wissenschaft*, 1882) -- whose title was inspired by the troubadour songs of southern-French Provence (1100-1300) -- Nietzsche set forth some of the existential ideas for which he became famous, namely, the proclamation that "God is dead" and the doctrine of "eternal recurrence"-- the idea that one is, or might be, fated to relive forever

every moment one one's life, with no omission whatsoever of any pleasurable or painful detail. Nietzsche's atheism -- his account of "God's murder" (section 125) -- was voiced in reaction to the conception of a single, ultimate, judgmental authority who is privy to everyone's hidden, and personally embarrassing, secrets; his atheism also aimed to redirect people's attention to their inherent freedom, the presently-existing world, and away from all escapist, pain-relieving, heavenly otherworlds. To a similar end, Nietzsche's doctrine of eternal recurrence (sections 285 and 341) was formulated to draw attention away from all worlds other than the one in which we presently live, since eternal recurrence precludes the possibility of any final escape from the present world. The doctrine also functions as a measure for judging someone's overall psychological strength and mental health, since Nietzsche believed that the doctrine of eternal recurrence was the hardest world-view to accept and affirm. In 1887, *The Gay Science* was reissued with an important preface, an additional fifth Book, and an appendix of songs, reminiscent of the troubadours.

Later-Period Writings: 1883-1887

Thus Spoke Zarathustra, A Book for All and None (*Also Sprach Zarathustra, Ein Buch für Alle und Keinen*, 1883-85), is one of Nietzsche's most famous works, and Nietzsche himself regarded it as among his most significant. It is, in effect, a manifesto of personal self-overcoming. Thirty years after its initial publication, 150,000 copies of the work were printed by the German government and issued as inspirational reading, along with the Bible, to the young soldiers during WWI. Though *Thus Spoke Zarathustra* is antagonistic to the Judeo-Christian world-view, its poetic and prophetic style relies upon many, often inverted, Old and New Testament allusions. Nietzsche also filled the work with nature metaphors, almost in the spirit of pre-Socratic naturalist philosophy, which invoked animals, earth, air, fire, water, celestial bodies, plants, all in the service of describing the spiritual development of Zarathustra, a solitary, reflective, exceedingly strong-willed, sage-like, laughing and dancing voice of self-mastery who, accompanied by a proud, sharp-eyed eagle and a wise snake, envisioned a mode of psychologically healthier being beyond the common human condition. Nietzsche refers to this higher mode of being as "superhuman" (*übermenschlich*), and associates the doctrine of eternal recurrence -- a doctrine for only the healthiest who can love life in its entirety -- with this spiritual standpoint, in relation to which all-too-often downhearted, all-too-commonly-human attitudes stand as a mere bridge to be crossed and overcome.

In *Beyond Good and Evil, Prelude to a Philosophy of the Future* (*Jenseits von Gut und Böse. Vorspiel einer Philosophie der Zukunft*, 1886), Nietzsche identified imagination, self-assertion, danger, originality and the "creation of values" as qualities of genuine philosophers, as opposed to incidental characters who engage in dusty scholarship. Nietzsche also took aim at some of the world's great philosophers's key presuppositions, who grounded their outlooks wholeheartedly upon concepts such as "self-consciousness," "free will," and "either/or" bipolar thinking. Alternatively, Nietzsche philosophizes from "the perspective of life" which he regards as "beyond good and evil," and challenges the deeply-entrenched moral idea that exploitation, domination, injury to the weak, destruction and appropriation are universally objectionable behaviors. Above all, Nietzsche believes that living things aim to discharge their strength and express their "will to power" -- a pouring-out of expansive energy which, quite

naturally, can entail danger, pain, lies, deception and masks. As he views things from the perspective of life, he further denies that there is a universal morality applicable indiscriminately to all human beings, and instead designates a series of moralities in an order of rank ranging from the noble to the plebeian: some moralities are more appropriate for dominating and leading social roles; some are more suitable for subordinate roles. So what counts as a preferable and legitimate action depends upon the kind of person one is. The deciding factor is whether one is strong, healthy, powerful and overflowing with ascending life, or whether one is weak, sick and on the decline.

On the Genealogy of Morals, A Polemic (*Zur Genealogie der Moral, Eine Streitschrift*, 1887), is composed of three sustained essays which advance the critique of Christianity expressed in *Beyond Good and Evil*. The first essay continues the discussion of master morality versus servant morality, and maintains that the traditional ideals set forth as holy and morally good within Christian morality are products of self-deception, since they were forged in the bad air of revenge, resentment, hatred, impotence, and cowardice. In this essay, as well as the next, Nietzsche's controversial references to the "blond beast" akin to master morality often appear. In the second essay, Nietzsche continues with an account of how feelings of guilt, or the "bad conscience," arise merely as a consequence of an unhealthy Christian morality which turns an "evil eye" towards our natural inclinations. He also discusses how punishment, conceived as the infliction of pain upon someone in proportion to their offense, is likely to have been grounded in the contractual economic relationship between creditor and debtor. In the third essay, Nietzsche focusses upon the ascetic ideals typical of the social representatives of art, religion and philosophy, and he offers a particularly scathing critique of the priesthood: the priests are allegedly a group of weak people who shepherd even weaker people as a way to experience power for themselves. The third essay also contains one of Nietzsche's clearest expressions of "perspectivism" (section 12) -- the idea that there is no absolute, "God's eye" standpoint from which one can survey everything that is.

Final Writings of 1888

The Case of Wagner, A Musician's Problem (*Der Fall Wagner, Ein Musikanten-Problem,* May-August 1888), compares well with Nietzsche's 1873 meditation on David Strauss in its devastating and unbridled attack on a popular cultural figure. In *The Case of Wagner,* Nietzsche "declares war" upon Richard Wagner, whose music is characterized as both the epitome of modern cultural achievement and as thoroughly sick and decadent. The work is a brilliant display of Nietzsche's talents as a music critic, and includes memorable mockings of Wagner's theatrical style, reflections on redemption via art, a "physiology of art," and the virtues associated, respectively, with ascending and descending life energies.

The title, *Twilight of the Idols, or How One Philosophizes with a Hammer* (*Götzen-Dämmerung, oder Wie man mit dem Hammer philosophiert*, August-September 1888), word-plays upon Wagner's opera, *The Twilight of the Gods* (*Die Götterdämmerung*). Nietzsche reiterates and elaborates some of the criticisms of Socrates, Plato, Kant and Christianity found in earlier works, criticizes the then-contemporary German culture as being unsophisticated and too-full of beer, and shoots some disapproving arrows at key French, British, and Italian cultural figures such as Rousseau, Hugo, Sand, Michelet, Zola, Renan, Carlyle, Mill, Eliot, Darwin, and Dante. In contrast to all these alleged

representatives of cultural decadence, Nietzsche applauds Caesar, Napoleon, Goethe, Dostoevski, Thucydides and the Sophists as healthier and stronger types.

In *The Antichrist, Curse on Christianity* (*Der Antichrist. Fluch auf das Christentum,* September 1888), Nietzsche expresses his disgust over the way noble values in Roman Society were "corrupted" by the rise of Christianity, and he discusses specific aspects and personages in Christian culture -- the Gospels, Paul, the martyrs, priests, the crusades -- with a view towards showing that Christianity is a religion for weak and unhealthy people, whose general historical effect has been to undermine the healthy qualities of the more noble cultures.

Nietzsche describes himself as "a follower of the philosopher Dionysus" in *Ecce Homo, How One Becomes What One Is* (*Ecce Homo, Wie man wird, was man ist*, October-November 1888) -- a book in which he examines retrospectively his entire corpus, work by work, offering critical remarks, details of how the works were inspired, and explanatory observations regarding their philosophical contents. He begins this fateful intellectual autobiography -- he was to lose his mind little more than a month later -- with three eyebrow-raising sections entitled, "Why I Am So Wise," "Why I Am So Clever," and "Why I Write Such Good Books." Nietzsche claims to be wise as a consequence of his acute aesthetic sensitivity to nuances of health and sickness in people’s attitudes and characters; he claims to be clever because he knows how to choose the right nutrition, climate, residence and recreation for himself; he claims to write such good books because they allegedly adventurously open up, at least for a very select group of readers, a new series of noble and delicate experiences. After examining each of his published works, Nietzsche concludes *Ecce Homo* with the section, "Why I Am a Destiny." He claims that he is a destiny because he regards his anti-moral truths as having the annihilating power of intellectual dynamite; he expects them to topple the morality born of sickness which he perceives to have been reigning within Western culture for the last two thousand years. In this way, Nietzsche expresses his hope that Dionysus, the god of life’s exuberance, would replace Jesus, the god of the heavenly otherworld, as the premier cultural standard for future millennia.

Nietzsche Contra Wagner, Out of the Files of a Psychologist (*Nietzsche contra Wagner, Aktenstücke eines Psychologen,* December 1888) is a short, but classic, selection of passages Nietzsche extracted from his 1878-1887 published works. Many concern Wagner, but the excerpts serve mostly as a foil for Nietzsche to express his own views against Wagner’s. In this self-portrait, completed only a month before his collapse, Nietzsche characterizes his own anti-Christian sentiments, and contemplates how even the greatest people usually undergo significant corruption. In Wagner’s case, Nietzsche claims that the corrupting force was Christianity. At the same time, Nietzsche describes how he truly admired some of Wagner’s music for its deep expressions of loneliness and suffering -- expressions which Nietzsche admitted were psychologically impossible for he himself to articulate.

Nietzsche’s Unpublished Notebooks

Nietzsche’s unpublished writings often reveal his more tentative and speculative ideas. This material is surrounded by controversy, however, since some of it conflicts dramatically with views Nietzsche

expresses in his published works. Disagreement regarding Nietzsche's notebooks, also known as his *Nachlass*, centers around the degree of interpretive priority which ought to be given to the unpublished versus the published manuscripts. One popular approach in the tradition of classical scholarly interpretation is to maintain that Nietzsche's published works express his more considered and polished views, and that these should take precedence over the unpublished manuscripts when conflicts arise; a second attitude, given voice by Martin Heidegger, and broadly consistent with a psychoanalytic approach as well, is to regard what Nietzsche published as representative of what he decided was publicly presentable, and what he kept privately to himself in unpublished form as containing his more authentic views; a third, more comprehensive, interpretive style tries to grasp all of Nietzsche's texts together in an effort to form the most coherent interpretation of Nietzsche's thought, judging the priority of published versus unpublished works on a thematic, or case-by-case basis; a fourth position influenced by the French deconstructionist perspective maintains that any rigid prioritizing between published and private works is impossible, since all of the texts embody a comparable multidimensionality of meaning.

In his unpublished manuscripts, Nietzsche sometimes elaborates the topics found in the published works, such as his early 1870's notebooks, where there is important material concerning his theory of knowledge. In the 1880's notebooks -- those his sister collected together after his death under the title, *The Will to Power: Attempt at a Revaluation of all Values* -- Nietzsche adopts a more metaphysical orientation towards the doctrines of Eternal Recurrence and the Will to Power, speculating upon their intellectual strength as interpretations of reality itself. Side-by-side with these speculations, and complicating efforts towards developing an interpretation which is both comprehensive and coherent, Nietzsche's 1880's notebooks also repeatedly state that "there are no facts, only interpretations."

Nietzsche's Influence Upon 20th Century Thought

Nietzsche's thought extended a deep influence during the 20th century, especially in Continental Europe. In English-speaking countries, his positive reception has been less resonant. During the last decade of Nietzsche's life and the first decade of the 20th century, his thought was particularly attractive to avant-garde artists who saw themselves on the periphery of established social fashion and practice. Here, Nietzsche's advocacy of new, healthy beginnings, and of creative artistry in general stood forth. His tendency to seek explanations for commonly-accepted values and outlooks in the less-elevated realms of sheer animal instinct was also crucial to Sigmund Freud's development of psychoanalysis. Later, during the 1930's, aspects of Nietzsche's thought were espoused by the Nazis and Italian Fascists, partly due to the encouragement of Elisabeth Förster-Nietzsche through her solicitations with Adolf Hitler and Benito Mussolini. It was possible for the Nazi interpreters to assemble, quite selectively, various passages from Nietzsche's writings whose juxtaposition appeared to justify war, aggression and domination for the sake of nationalistic and racial self-glorification. Until the 1960's in France, Nietzsche appealed mainly to writers and artists, since the academic philosophical climate was dominated by G.W.F. Hegel's, Edmund Husserl's and Martin Heidegger's thought, along with the structuralist movement of the 1950's. Nietzsche became especially influential in French philosophical circles during the 1960's-1980's, when his "God is dead" declaration, his perspectivism, and his emphasis upon power as the real motivator and explanation for people's actions revealed new ways to challenge established authority and launch

effective social critique.

Specific 20th century figures who were influenced, either quite substantially, or in a significant part, by Nietzsche include painters, dancers, musicians, playwrights, poets, novelists, psychologists, sociologists, literary theorists, historians, and philosophers: Alfred Adler, Georges Bataille, Martin Buber, Albert Camus, E.M. Cioran, Jacques Derrida, Gilles Deleuze, Isadora Duncan, Michel Foucault, Sigmund Freud, Stefan George, André Gide, Hermann Hesse, Carl Jung, Martin Heidegger, Gustav Mahler, André Malraux, Thomas Mann, Rainer Maria Rilke, Jean-Paul Sartre, Max Scheler, Giovanni Segantini, George Bernard Shaw, Lev Shestov, Georg Simmel, Oswald Spengler, Paul Tillich, Ferdinand Tönnies, Mary Wigman, William Butler Yeats and Stefan Zweig.

That Nietzsche was able to write so prolifically and profoundly for years, while remaining in a condition of ill-health and often intense physical pain, is a testament to his spectacular mental capacities and willpower. Lesser people under the same physical pressures might not have had the inclination to pick up a pen, let alone think and record thoughts which -- created in the midst of striving for healthy self-overcoming -- would have the power to influence an entire century.

Bibliography

A. Nietzsche’s Writings

- *Kritische Gesamtausgabe Briefwechsel.* ed. G. Colli and M. Montinari, 24 vols. in 4 parts. Berlin: Walter de Gruyter, 1975.
- *The Antichrist.* trans. Walter Kaufmann, in *The Portable Nietzsche*, ed. Walter Kaufmann. New York: Viking Press, 1968.
- *Beyond Good and Evil*. trans. Walter Kaufmann. New York: Random House, 1966.
- *The Birth of Tragedy*. trans. Walter Kaufmann, in *The Birth of Tragedy and The Case of Wagner*. New York: Random House, 1967.
- *The Case of Wagner*. trans. Walter Kaufmann, in *The Birth of Tragedy and The Case of Wagner*. New York: Random House, 1967.
- Daybreak: Thoughts on the Prejudices of Morality. trans. R. J. Hollingdale. Cambridge: Cambridge University Press, 1982.
- *Ecce Homo: How One Becomes What One Is*. trans. Walter Kaufmann, in *On the Genealogy of Morals and Ecce Homo*. New York: Random House, 1967.
- *The Gay Science, with a Prelude of Rhymes and an Appendix of Songs*. tr. Walter Kaufmann. New York: Random House, 1974.
- *Human, All Too Human: A Book for Free Spirits*. trans. R. J. Hollingdale. Cambridge: Cambridge University Press, 1986.
- *Nietzsche Contra Wagner*. trans. Walter Kaufmann, in *The Portable Nietzsche*. New York: Viking Press, 1968.
- *On the Genealogy of Morals*. trans. Walter Kaufmann and R.J. Hollingdale, in *On the Genealogy*

of Morals and Ecce Homo. New York: Random House, 1967.

- *Philosophy and Truth: Selections from Nietzsche's Notebooks of the Early 1870's*. trans. and ed. Daniel Breazeale. Atlantic Highlands, N.J.: Humanities Press, 1979.
- *Philosophy in the Tragic Age of the Greeks*. trans. Marianne Cowan. Chicago: Henry Regnery Company, 1962.
- *Thus Spoke Zarathustra*. trans. Walter Kaufmann, in *The Portable Nietzsche*. New York: Viking Press, 1968.
- *Twilight of the Idols*. trans. Walter Kaufmann, in *The Portable Nietzsche*. New York: Viking Press, 1968.
- *Untimely Meditations*. trans. R. J. Hollingdale. Cambridge: Cambridge University Press, 1983.

Bertrand Russell

Bertrand Arthur William Russell (b.1872 - d.1970), British philosopher, logician, essayist, and social critic, best known for his work in mathematical logic and analytic philosophy. His most influential contributions include his defense of logicism (the view that mathematics is in some important sense reducible to logic), and his theories of definite descriptions and logical atomism. Along with G.E. Moore, Russell is generally recognized as one of the founders of analytic philosophy. Along with Kurt Gödel, he is also often credited with being one of the two most important logicians of the twentieth century.

Over the course of his long career, Russell made significant contributions, not just to logic and philosophy, but to a broad range of other subjects (including education, politics, history, religion and science), and many of his writings on a wide variety of topics have influenced generations of general readers. After a life marked by controversy (including dismissals from both Trinity College, Cambridge, and City College, New York), Russell was awarded the Order of Merit in 1949 and the Nobel Prize for Literature in 1950. Also noted for his many spirited anti-war and anti-nuclear protests, Russell remained a prominent public figure until his death at the age of 97.

For an excellent short introduction to Russell's life, work and influence the reader is encouraged to consult John Slater's accessible and informative *Bertrand Russell* (Bristol: Thoemmes, 1994).

For a complete list of Russell's publications see *A Bibliography of Bertrand Russell* (3 vols, London: Routledge, 1994), by Kenneth Blackwell and Harry Ruja. A less detailed, but still comprehensive, list appears in Paul Arthur Schilpp, *The Philosophy of Bertrand Russell*, 3rd ed., (New York: Harper and

Row, 1963), pp. 746-803.

For a bibliography of the secondary literature surrounding Russell, see A.D. Irvine (ed.), *Bertrand Russell: Critical Assessments*, Vol. 1, (London: Routledge, 1998), pp. 247-312.

A Chronology of Russell's Life

A short chronology of the major events in Russell's life is as follows:

- (1872) Born May 18 at Ravenscroft, Wales.
- (1874) Death of mother and sister.
- (1876) Death of father; Russell's grandfather, Lord John Russell (the former Prime Minister), and grandmother succeed in overturning his father's will to win custody of Russell and his brother.
- (1878) Death of grandfather; Russell's grandmother, Lady Russell, supervises his upbringing.
- (1890) Enters Trinity College, Cambridge.
- (1893) Awarded first class B.A. in Mathematics.
- (1894) Completed the Moral Sciences Tripos (Part II)
- (1894) Marries Alys Pearsall Smith.
- (1900) Meets Peano at International Congress in Paris.
- (1901) Discovers Russell's paradox.
- (1902) Corresponds with Frege.
- (1908) Elected Fellow of the Royal Society.
- (1916) Fined 110 pounds and dismissed from Trinity College as a result of anti-war protests.
- (1918) Imprisoned for six months as a result of anti-war protests.
- (1921) Divorce from Alys and marriage to Dora Black.
- (1927) Opens experimental school with Dora.
- (1931) Becomes the third Earl Russell upon the death of his brother.
- (1935) Divorce from Dora.
- (1936) Marriage to Patricia (Peter) Helen Spence.

- (1940) Appointment at City College New York revoked following public protests.
- (1943) Dismissed from Barnes Foundation in Pennsylvania.
- (1949) Awarded the Order of Merit.
- (1950) Awarded Nobel Prize for Literature.
- (1952) Divorce from Peter and marriage to Edith Finch.
- (1955) Releases Russell-Einstein Manifesto.
- (1957) Organizes the first Pugwash Conference.
- (1958) Becomes founding President of the Campaign for Nuclear Disarmament.
- (1961) Imprisoned for one week in connection with anti-nuclear protests.
- (1970) Dies February 02 at Penrhyndeudraeth, Wales.

For a chronology of Russell's major publications, consult the section below entitled Russell's Writings.

For more detailed information about Russell's life, the reader is encouraged to consult, in the first instance, Russell's four autobiographical volumes, *My Philosophical Development* (London: George Allen & Unwin, 1959) and *The Autobiography of Bertrand Russell* (3 vols, London: George Allen & Unwin, 1967, 1968, 1969).

Other sources of biographical information include Ronald Clark, *The Life of Bertrand Russell* (London: J. Cape, 1975), A.D. Irvine (ed.), *Bertrand Russell: Critical Assessments*, Vol. 1, (London: Routledge, 1998), and Ray Monk, *Bertrand Russell: The Spirit of Solitude* (London: J. Cape, 1996).

Russell's Work in Logic

Russell's contributions to logic and the foundations of mathematics include his discovery of Russell's paradox, his defense of logicism (the view that mathematics is, in some significant sense, reducible to formal logic), his development of the theory of types, and his refining of the first-order predicate calculus.

Russell discovered the paradox that bears his name in 1901, while working on his *Principles of Mathematics* (1903). The paradox arises in connection with the set of all sets that are not members of themselves. Such a set, if it exists, will be a member of itself if and only if it is not a member of itself. The paradox is significant since, using classical logic, all sentences are entailed by a contradiction. Russell's discovery thus prompted a large amount of work in logic, set theory, and the philosophy and foundations of mathematics.

Russell's own response to the paradox came with the development of his theory of types in 1903. It was clear to Russell that some restrictions needed to be placed upon the original comprehension (or abstraction) axiom of naive set theory, the axiom which formalized the intuition that any coherent condition may be used to determine a set (or class). Russell's basic idea was that reference to sets such as the set of all sets that are not members of themselves could be avoided by arranging all sentences into a

hierarchy (beginning with sentences about individuals at the lowest level, sentences about sets of individuals at the next lowest level, sentences about sets of sets of individuals at the next lowest level, etc.). Using a vicious circle principle similar to that adopted by the mathematician Henri Poincaré, and his own so-called "no class" theory of classes, Russell was able to explain why the unrestricted comprehension axiom fails: propositional functions, such as the function "*x* is a set", may not be applied to themselves since self-application would involve a vicious circle. Thus, on Russell's view, all objects for which a given condition (or predicate) holds must be at the same level or of the same "type".

Although first introduced in 1903, the theory of types finds its mature expression in Russell's 1908 article "Mathematical Logic as Based on the Theory of Types" and in the monumental work he co-authored with Alfred North Whitehead, *Principia Mathematica* (1910, 1912, 1913). Thus the theory admits of two versions, the "simple theory" and the "ramified theory". Both versions of the theory later came under attack for being both too weak and too strong. For some, the theory was too weak since it failed to resolve all of the known paradoxes. For others, it was too strong since it disallowed many mathematical definitions which, although consistent, violated the vicious circle principle. Russell's response was to introduce the axiom of reducibility, an axiom that lessened the vicious circle principle's scope of application, but which many people claimed was too ad hoc to be justified philosophically.

Of equal significance during this same period was Russell's defense of logicism, the theory that mathematics was in some important sense reducible to logic. First defended in his *Principles of Mathematics*, and later in greater detail in *Principia Mathematica*, Russell's logicism consisted of two main theses. The first is that all mathematical truths can be translated into logical truths or, in other words, that the vocabulary of mathematics constitutes a proper subset of that of logic. The second is that all mathematical proofs can be recast as logical proofs or, in other words, that the theorems of mathematics constitute a proper subset of those of logic.

Like Gottlob Frege, Russell's basic idea for defending logicism was that numbers may be identified with classes of classes and that number-theoretic statements may be explained in terms of quantifiers and identity. Thus the number 1 would be identified with the class of all unit classes, the number 2 with the class of all two-membered classes, and so on. Statements such as "There are two books" would be recast as statements such as "There is a book, *x*, and there is a book, *y*, and *x* is not identical to *y*". It followed that number theoretic operations could be explained in terms of set theoretic operations such as intersection, union, and difference. In *Principia Mathematica*, Whitehead and Russell were able to provide many detailed derivations of major theorems in set theory, finite and transfinite arithmetic, and elementary measure theory. A fourth volume on geometry was planned but never completed.

Russell's most important writings relating to these topics include not only *Principles of Mathematics* (1903), "Mathematical Logic as Based on the Theory of Types" (1908), and *Principia Mathematica* (1910, 1912, 1913), but also his *An Essay on the Foundations of Geometry* (1897), and *Introduction to Mathematical Philosophy* (1919).

Russell's Work in Analytic Philosophy

In much the same way that Russell used logic in an attempt to clarify issues in the foundations of mathematics, he also used logic in an attempt to clarify issues in philosophy. As one of the founders of analytic philosophy, Russell made significant contributions to a wide variety of areas, including metaphysics, epistemology, ethics and political theory, as well as to the history of philosophy. Underlying these various projects was not only Russell's use of logical analysis, but also his long-standing aim of discovering whether, and to what extent, knowledge is possible. "There is one great question," he writes in 1911. "Can human beings *know* anything, and if so, what and how? This question is really the most essentially philosophical of all questions."[1]

More than this, Russell's various contributions were also unified by his views concerning both the centrality of scientific knowledge and the importance of an underlying scientific methodology that is common to both philosophy and science. In the case of philosophy, this methodology expressed itself through Russell's use of logical analysis. In fact, Russell often claimed that he had more confidence in his methodology than in any particular philosophical conclusion.

Russell's conception of philosophy arose in part from his idealist origins.[2] This is so even though he believed that his one, true revolution in philosophy came with his break from idealism. Russell saw that the idealist doctrine of internal relations led to a series of contradictions regarding asymmetrical (and other) relations necessary for mathematics. Thus, in 1898, he abandoned idealism and his Kantian methodology in favour of a pluralistic realism. Emerging from the idealism that he had encountered as a student at Cambridge, Russell became famous for his defense of the "new realism" and for his "new philosophy of logic", emphasizing as it did the importance of modern logic for philosophical analysis. The underlying themes of this "revolution", such as his belief in pluralism, his emphasis upon anti-psychologism, and the importance of science, remained central to Russell's philosophy for the remainder of his life.[3]

Russell's methodology consisted of the making and testing of hypotheses through the weighing of evidence (hence Russell's comment that he wished to emphasize the "scientific method" in philosophy[4]), together with a rigorous analysis of problematic propositions using the machinery of first-order logic. It was Russell's belief that by using the new logic of his day, philosophers would be able to exhibit the underlying "logical form" of natural language statements. A statement's logical form, in turn, would help philosophers resolve problems of reference associated with the ambiguity and vagueness of natural language. Thus, just as we distinguish three separate sense of "is" -- the is of predication, the is of identity, and the is of existence -- and exhibit these three senses by using three separate logical notations -- Px, $x=y$, and $\exists x$ respectively -- we will also discover other ontologically significant distinctions by being aware of a sentence's correct logical form. On Russell's view, the subject matter of philosophy is then distinguished from that of the sciences only by the generality and the *a prioricity* of philosophical statements, not by the underlying methodology of the discipline. In philosophy, as in mathematics, Russell believed that it was by applying logical machinery and insights that advances would be made.

Russell's most famous example of his "analytic" methodology concerns denoting phrases such as

descriptions and proper names. In his *Principles of Mathematics*, Russell had adopted the view that every denoting phrase (for example, "Scott", "blue", "the number two", "the golden mountain") was assumed to refer to an existing entity. By the time his landmark article, "On Denoting", appeared two years later, in 1905, Russell had modified this extreme realism and had instead become convinced that denoting phrases need not possess a theoretical unity. While logically proper names (words such as "this" or "that" which refer to sensations of which an agent is immediately aware) do have referents associated with them, descriptive phrases (such as "the smallest number less than pi") should be viewed a collection of quantifiers (such as "all" and "some") and propositional functions (such as "x is a number"). As such, they are not to be viewed as referring terms but, rather, as "incomplete symbols". In other words, they should be viewed as symbols that take on meaning within appropriate contexts, but that are meaningless in isolation.

Thus, in the sentence

> (1) The present King of France is bald,

the definite description "The present King of France" plays a role quite different from that of a proper name such as "Scott" in the sentence

> (2) Scott is bald.

Letting K abbreviate the predicate "is a present King of France" and B abbreviate the predicate "is bald", Russell assigns sentence (1) the logical form

> (1′) There is an x such that (i) Kx, (ii) for any y, if Ky then $y=x$, and (iii) Bx.

Alternatively, in the notation of the predicate calculus, we have

$$\exists x[Kx \ \& \ \forall y(Ky \rightarrow y=x) \ \& \ Bx].$$

In contrast, by allowing s to abbreviate the name "Scott", Russell assigns sentence (2) the very different logical form

> (2′) Bs.

This distinction between various logical forms allows Russell to explain three important puzzles. The first concerns the operation of the Law of Excluded Middle and how this law relates to denoting terms. According to one reading of the Law of Excluded Middle, it must be the case that either "The present King of France is bald" is true or "The present King of France is not bald" is true. But if so, both sentences appear to entail the existence of a present King of France, clearly an undesirable result. Russell's analysis shows how this conclusion can be avoided. By appealing to analysis (1′), it follows that there is a way to deny (1) without being committed to the existence of a present King of France,

namely by accepting that "It is not the case that there exists a present King of France who is bald" is true.

The second puzzle concerns the Law of Identity as it operates in (so-called) opaque contexts. Even though "Scott is the author of *Waverley*" is true, it does not follow that the two referring terms "Scott" and "the author of *Waverley*" are interchangeable in all contexts. Thus although "George wanted to know whether Scott was the the author of *Waverley*" is true, "George wanted to know whether Scott was Scott" is, presumably, false. Russell's distinction between the logical forms associated with the use of proper names and definite descriptions shows why this is so.

To see this we once again let s abbreviate the name "Scott". We also let w abbreviate "*Waverley*" and A abbreviate the two-place predicate "is the author of". It then follows that the sentence

(3) $s=s$

is not equivalent to the sentence

(4) $\exists x[Axw \,\&\, \forall y(Ayw \rightarrow y=x) \,\&\, x=s]$.

The third puzzle relates to true negative existential claims, such as the claim "The golden mountain does not exist". Here, once again, by treating definite descriptions as having a logical form distinct from that of proper names, Russell is able to give an account of how a speaker may be committed to the truth of a negative existential without also being committed to the belief that the subject term has reference. That is, the claim that Scott does not exist is false since

(5) $\sim\exists x(x=s)$

is self-contradictory. (After all, there must exist something that is identical to s since it is a logical truth that s is identical to itself!) In contrast, the claim that a golden mountain does not exist may be true since, assuming that G abbreviates the predicate "is golden" and M abbreviates the predicate "is a mountain", there is nothing contradictory about

(6) $\sim\exists x(Gx \,\&\, Mx)$.

Russell's emphasis upon logical analysis also had consequences for his metaphysics. In response to the traditional problem of the external world which, it is claimed, arises since the external world can be known only by inference, Russell developed his famous 1910 distinction between "knowledge by acquaintance and knowledge by description". He then went on, in his 1918 lectures on logical atomism, to argue that the world itself consists of a complex of logical atoms (such as "little patches of colour") and their properties. Together they form the atomic facts which, in turn, are combined to form logically complex objects. What we normally take to be inferred entities (for example, enduring physical objects) are then understood to be "logical constructions" formed from the immediately given entities of sensation, viz., "sensibilia". It is only these latter entities that are known non-inferentially and with

certainty. According to Russell, the philosopher's job is to discover a logically ideal language that will exhibit the true nature of the world in such a way that the speaker will not be misled by the casual surface structure of natural language. Just as atomic facts (the association of universals with an appropriate number of individuals) may be combined into molecular facts in the world itself, such a language would allow for the description of such combinations using logical connectives such as "and" and "or". In addition to atomic and molecular facts, Russell also held that general facts (facts about "all" of something) were needed to complete the picture of the world. Famously, he vacillated on whether negative facts were also required.

Russell's most important writings relating to these topics include not only "On Denoting" (1905), but also his "Knowledge by Acquaintance and Knowledge by Description" (1910), "The Philosophy of Logical Atomism" (1918, 1919), "Logical Atomism" (1924), *The Analysis of Mind* (1921), and *The Analysis of Matter* (1927).

Russell's Social and Political Philosophy

Russell's social influence stems from three main sources: his long-standing social activism, his many writings on the social and political issues of his day, and his popularizations of technical writings in philosophy and the natural sciences.

Among Russell's many popularizations are his two best selling works, *The Problems of Philosophy* (1912) and *A History of Western Philosophy* (1945). Both of these books, as well as his numerous but less famous books popularizing science, have done much to educate and inform generations of general readers. Naturally enough, Russell saw a link between education, in this broad sense, and social progress. At the same time, Russell is also famous for suggesting that a widespread reliance upon evidence, rather than upon superstition, would have enormous social consequences: "I wish to propose for the reader's favourable consideration," says Russell, "a doctrine which may, I fear, appear wildly paradoxical and subversive. The doctrine in question is this: that it is undesirable to believe a proposition when there is no ground whatever for supposing it true."[5]

Still, Russell is best known in many circles as a result of his campaigns against the proliferation of nuclear weapons and against western involvement in the Vietnam War during the 1950s and 1960s. However, Russell's social activism stretches back at least as far as 1910, when he published his *Anti-Suffragist Anxieties,* and to 1916, when he was convicted and fined in connection with anti-war protests during World War I. Following his conviction, he was also dismissed from his post at Trinity College, Cambridge. Two years later, he was convicted a second time. The result was six months in prison. Russell also ran unsuccessfully for Parliament (in 1907, 1922, and 1923) and, together with his second wife, founded and operated an experimental school during the late 1920s and early 1930s.

Although he became the third Earl Russell upon the death of his brother in 1931, Russell's radicalism continued to make him a controversial figure well through middle-age. While teaching in the United States in the late 1930s, he was offered a teaching appointment at City College, New York. The

appointment was revoked following a large number of public protests and a 1940 judicial decision which found him morally unfit to teach at the College.

In 1954 he delivered his famous "Man's Peril" broadcast on the BBC, condemning the Bikini H-bomb tests. A year later, together with Albert Einstein, he released the Russell-Einstein Manifesto calling for the curtailment of nuclear weapons. In 1957 he was a prime organizer of the first Pugwash Conference, which brought together a large number of scientists concerned about the nuclear issue. He became the founding president of the Campaign for Nuclear Disarmament in 1958 and was once again imprisoned, this time in connection with anti-nuclear protests in 1961. The media coverage surrounding his conviction only served to enhance Russell's reputation and to further inspire the many idealistic youths who were sympathetic to his anti-war and anti-nuclear protests.

During these controversial years Russell also wrote many of the books that brought him to the attention of popular audiences. These included his *Principles of Social Reconstruction* (1916), *A Free Man's Worship* (1923), *On Education* (1926), *Why I Am Not a Christian* (1927), *Marriage and Morals* (1929), *The Conquest of Happiness* (1930), *The Scientific Outlook* (1931), and *Power: A New Social Analysis* (1938).

Upon being awarded the Nobel Prize for Literature in 1950, Russell used his acceptance speech to emphasize, once again, themes related to his social activism and to warn of the dangers associated with nuclear war.

The Collected Papers of Bertrand Russell

The Bertrand Russell Editorial Project is currently in the process of publishing Russell's *Collected Papers.* When complete, these volumes will bring together all of Russell's writings, excluding his correspondence and previously published monographs.

In Print

- Vol. 1: *Cambridge Essays, 1888-99,* London, Boston, Sydney: George Allen & Unwin, 1983.
- Vol. 2: *Philosophical Papers, 1896-99,* London and New York: Routledge, 1990.
- Vol. 3: *Toward the Principles of Mathematics,* London and New York: Routledge, 1994.
- Vol. 4: *Foundations of Logic, 1903-05,* London and New York: Routledge, 1994.
- Vol. 6: *Logical and Philosophical Papers, 1909-13,* London and New York: Routledge, 1992.
- Vol. 7: *Theory of Knowledge: The 1913 Manuscript*, London, Boston, Sydney: George Allen & Unwin, 1984.
- Vol. 8: *The Philosophy of Logical Atomism and Other Essays, 1914-19,* London: George Allen & Unwin, 1986.
- Vol. 9: *Essays on Language, Mind and Matter, 1919-26,* London: Unwin Hyman, 1988.
- Vol. 10: *A Fresh Look at Empricism, 1927-42,* London and New York: Routledge, 1996.
- Vol. 11: *Last Philosophical Testament, 1943-68,* London and New York: Routledge, 1997.
- Vol. 12: *Contemplation and Action, 1902-14,* London, Boston, Sydney: George Allen & Unwin, 1985.
- Vol. 13: *Prophecy and Dissent, 1914-16,* London: Unwin Hyman, 1988.
- Vol. 14: *Pacifism and Revolution, 1916-18,* London and New York: Routledge, 1995.
- Vol. 15: *Uncertain Paths to Freedom: Russia and China, 1919-1922,* London and New York: Routledge, 2000.

Planned and Forthcoming

- Vol. 5: *Toward Principia Mathematica, 1906-08.*
- Vol. 16: *Labour and Internationalism, 1922-24.*
- Vol. 17: *Behaviourism and Education, 1925-28.*
- Vol. 18: *Science, Sex and Society, 1929-31.*
- Vol. 19: *Fascism and Other Depression Legacies, 1931-33.*
- Vol. 20: *Fascism and Other Depression Legacies, 1933-34.*
- Vol. 21: *How to Keep the Peace: The Pacifist Dilemma, 1934-36.*
- Vol. 22: *The Superior Virtue of the Oppressed and Other Essays, 1936-39.*
- Vol. 23: *The Problems of Democracy, 1940-44.*
- Vol. 24: *Civilization and the Bomb, 1944-47.*
- Vol. 25: *Civilization and the Bomb, 1948-50.*
- Vol. 26: *Respectability At Last, 1950-51.*
- Vol. 27: *Respectability At Last, 1952-53.*
- Vol. 28: *Man's Peril, 1954-56.*
- Vol. 29: *The Campaign for Nuclear Disarmament, 1957-60.*
- Vol. 30: *A New Plan for Peace and Other Essays, 1960-64.*

- Vol. 31: *The Vietnam Campaign, 1965-70.*
- Vol. 32: *Newly Discovered Papers.*
- Vol. 33: *Indexes.*

Russell's Paradox

Russell's paradox is the most famous of the logical or set-theoretical paradoxes. The paradox arises within naive set theory by considering the set of all sets that are not members of themselves. Such a set appears to be a member of itself if and only if it is not a member of itself, hence the paradox.

Some sets, such as the set of all teacups, are not members of themselves. Other sets, such as the set of all non-teacups, are members of themselves. Call the set of all sets that are not members of themselves *S*. If *S* is a member of itself, then by definition it must not be a member of itself. Similarly, if *S* is not a member of itself, then by definition it must be a member of itself. Discovered by Bertrand Russell in 1901, the paradox has prompted much work in logic, set theory and the philosophy and foundations of mathematics.

History of the paradox

Russell appears to have discovered his paradox in May of 1901[1] while working on his *Principles of Mathematics* (1903). Cesare Burali-Forti, an assistant to Giuseppe Peano, had discovered a similar antinomy in 1897 when he noticed that since the set of ordinals is well-ordered, it, too, must have an ordinal. However, this ordinal must be both an element of the set of all ordinals and yet greater than every such element.

Russell wrote to Gottlob Frege with news of his paradox on June 16, 1902. The paradox was of significance to Frege's logical work since, in effect, it showed that the axioms Frege was using to formalize his logic were inconsistent. Specifically, Frege's Rule V, which states that two sets are equal if and only if their corresponding functions coincide in values for all possible arguments, requires that an expression such as $f(x)$ be considered both a function of the argument f and a function of the argument x.

In effect, it was this ambiguity that allowed Russell to construct S in such a way that it could both be and not be a member of itself.

Russell's letter arrived just as the second volume of Frege's *Grundgesetze der Arithmetik* (*The Basic Laws of Arithmetic*, 1893, 1903) was in press. Immediately appreciating the difficulty that the paradox posed, Frege hastily added an appendix to the *Grundgesetze* to discuss Russell's discovery. In this appendix Frege observes that the consequences of Russell's paradox are not immediately clear. For example, "Is it always permissible to speak of the extension of a concept, of a class? And if not, how do we recognize the exceptional cases? Can we always infer from the extension of one concept's coinciding with that of a second, that every object which falls under the first concept also falls under the second? These are questions," Frege notes, that have been "raised by Mr Russell's communication."[2]

Because of these kinds of worries, Frege eventually felt forced to abandon many of his views. Russell himself was also concerned about the paradox and so, like Frege, he hastily composed an appendix for his soon to be released *Principles of Mathematics*. Entitled "Appendix B: The Doctrine of Types", the appendix represents Russell's first attempt at developing a workable theory of types.

Significance of the paradox

The significance of Russell's paradox can be seen once it is realized that, using classical logic, all sentences follow from a contradiction. (For example, assuming both P and $\sim P$, we can prove any arbitrary Q as follows: from P we can obtain $P \vee Q$ by the rule of Addition, and then from $P \vee Q$ and $\sim P$ we can obtain Q by the rule of Disjunctive Syllogism.) In the eyes of many, it therefore appeared that no mathematical proof could be trusted once it was discovered that the set theory underlying all of mathematics was contradictory.

Russell's paradox stems from the idea that any coherent condition may be used to determine a set. Attempts at resolving the paradox therefore typically have concentrated on various means of restricting the principles governing the existence of sets. Naive set theory contained the so-called unrestricted comprehension (or abstraction) axiom. This is an axiom to the effect that any predicate expression, $P(x)$, containing x as a free variable will determine a set. The set's members will be exactly those objects that satisfy $P(x)$, namely every x that is P.[3] It is now generally agreed that such an axiom must be either abandoned or modified.[4]

Russell's response to the paradox is contained in his so-called *theory of types*. His basic idea is that we can avoid reference to S (the set of all sets that are not members of themselves) by arranging all sentences into a hierarchy. This hierarchy will consist of sentences (at the lowest level) about individuals, sentences (at the next lowest level) about sets of individuals, sentences (at the next lowest level) about sets of sets of individuals, etc. It is then possible to refer to all objects for which a given condition (or predicate) holds only if they are all at the same level or of the same "type".

This solution depends upon the assumption, often called the *vicious circle principle*, that the meaning of a propositional function cannot be specified until one specifies the exact range of objects which are candidates for satisfying it. From this it follows that these objects cannot meaningfully include anything that is defined in terms of the function itself. The result is that propositional functions, and their corresponding propositions, will need to be arranged in a hierarchy of the kind Russell proposes.

Although Russell first introduced the idea of a theory of types in his *Principles of Mathematics*, type-theory found its mature expression five years later in his 1908 article "Mathematical Logic as Based on the Theory of Types" and in the monumental work he co-authored with Alfred North Whitehead, *Principia Mathematica* (1910, 1912, 1913). In its details, Russell's type theory thus came to admit of two versions, the "simple theory" and the "ramified theory". Both versions have been criticized for being too ad hoc to eliminate the paradox successfully.

Other responses to the paradox include those of David Hilbert and the formalists (whose basic idea was to allow the use of only finite, well-defined and constructible objects, together with rules of inference that were deemed to be absolutely certain), and of Luitzen Brouwer and the intuitionists (whose basic idea was that one cannot assert the existence of a mathematical object unless one can also indicate how to go about constructing it).

Yet a fourth response to the paradox was Ernst Zermelo's 1908 axiomatization of set theory. Zermelo's axioms were designed to resolve Russell's paradox by restricting the naive comprehension principle. ZF, the axiomatization generally used today, is a modification of Zermelo's theory developed primarily by Abraham Fraenkel.

These four responses to the paradox have helped logicians develop an explicit awareness of the nature of formal systems and of the kinds of metalogical results that are today commonly associated with them.

Stanford Encyclopedia of Philosophy
Notes to Russell's Paradox

Notes

1. Exactly when the discovery of the paradox took place is not completely clear. Russell initially states that he came across the paradox "in June 1901" (see Russell 1944, p. 13). Later he reports that the discovery took place "in the spring of 1901" (see Russell 1959, p. 58). Later still he reports that he came across the paradox, not in June, but in May of that year (see Russell 1967/1968/1969, volume 3 (1969), p. 221).

2. See Frege 1903, p. 127.

3. It is worth noting that even prior to Russell's discovery this principle had not been universally accepted. Georg Cantor, for example, rejected it in favour of what was, in effect, a distinction between sets and classes, recognizing that some properties (such as the property of being an ordinal) produced collections that were too big to be sets, and that an assumption to the contrary would result in an inconsistent theory. (For further details see Menzel 1984, Moore 1982, and Hallett 1984.)

4. One exception is paraconsistent set theory. Paraconsistent set theory retains an unrestricted comprehension axiom but abandons classical logic, substituting a paraconsistent logic in its place. See the entries on paraconsistent logic and inconsistent mathematics in this Encyclopedia.

Paraconsistent Logic

The development of *paraconsistent logic* was initiated in order to challenge the logical principle that anything follows from contradictory premises, *ex contradictione quodlibet (ECQ)*. Let $\models$ be a relation of logical consequence, defined either semantically or proof-theoretically. Let us say that $\models$ is *explosive* iff for every formula *A* and *B*, {*A* , ~*A*} $\models$ *B*. Classical logic, intuitionistic logic, and most other standard logics are explosive. A logic is said to be *paraconsistent* iff its relation of logical consequence is not explosive.

The modern history of paraconsistent logic is relatively short. Yet the subject has already been shown to be an important development in logic for many reasons. These involve the motivations for the subject, its philosophical implications and its applications. In the first half of this article, we will review some of these. In the second, we will give some idea of the basic technical constructions involved in paraconsistent logics. Further discussion can be found in the references given at the end of the article.

Motivation and Applications

Inconsistent but Non-Trivial Theories

A most telling reason for paraconsistent logic is the fact that there are theories which are inconsistent but non-trivial. Clearly, once we admit the existence of such theories, their underlying logics must be paraconsistent. Examples of inconsistent but non-trivial theories are easy to produce. An example can be derived from the history of science. (In fact, many examples can be given from this area.) Consider Bohr's theory of the atom. According to this, an electron orbits the nucleus of the atom without radiating energy. However, according to Maxwell's equations, which formed an integral part of the theory, an electron which is accelerating in orbit must radiate energy. Hence Bohr's account of the behaviour of the atom was inconsistent. Yet, patently, not everything concerning the behavior of electrons was inferred from it. Hence, whatever inference mechanism it was that underlay it, this must have been paraconsistent.

Dialetheias (True Contradictions)

The importance of paraconsistent logic also follows if, more contentiously, but as some people have argued, there are true contradictions (dialetheias), i.e., there are sentences, *A*, such that both *A* and ~*A* are true. If there are dialetheias then some inferences of the form $\{A, \sim A\} \models B$ must fail. For only true conclusions follow validly from the true premises. Hence logic has to be paraconsistent. A plausible example of dialetheia is the *liar paradox*. Consider the sentence: This sentence is not true. There are two options: either the sentence is true or it is not. Suppose it is true. Then what it says is the case. Hence the sentence is not true. Suppose, on the other hand, it is not true. This is what it says. Hence the sentence is true. In either case it is both true and not true.

Automated Reasoning

Paraconsistent logic is motivated not only by philosophical considerations, but also by its applications and implications. One of the applications is *automated reasoning* (*information processing*). Consider a computer which stores a large amount of information. While the computer stores the information, it is also used to operate on it, and, crucially, to infer from it. Now it is quite common for the computer to contain inconsistent information, because of mistakes by the data entry operators or because of multiple sourcing. This is certainly a problem for database operations with theorem-provers, and so has drawn much attention from computer scientists. Techniques for removing inconsistent information have been investigated. Yet all have limited applicability, and, in any case, are not guaranteed to produce consistency. (There is no algorithm for logical falsehood.) Hence, even if steps are taken to get rid of contradictions when they are found, an underlying paraconsistent logic is desirable if hidden contradictions are not to generate spurious answers to queries.

Belief Revision

As a part of artificial intelligence research, *belief revision* is one of the areas that have been studied widely. Belief revision is the study of rationally revising bodies of belief in the light of new evidence.

Notoriously, people have inconsistent beliefs. They may even be rational in doing so. For example, there may be apparently overwhelming evidence for both something and its negation. There may even be cases where it is in principle impossible to eliminate such inconsistency. For example, consider the "paradox of the preface". A rational person, after thorough research, writes a book in which they claim $A_1, \ldots, A_n$. But they are also aware that no book of any complexity contains only truths. So they rationally believe $\sim(A_1 \;\&\; \ldots \;\&\; A_n)$ too. Hence, principles of rational belief revision must work on inconsistent sets of beliefs. Standard accounts of belief revision, e.g., that of Gärdenfors *et al.*, all fail to do this since they are based on classical logic. A more adequate account is based on a paraconsistent logic.

Mathematical Significance

Other applications of paraconsistent logic concern theories of mathematical significance. Examples of such theories are formal *semantics* and *set theory*.

Semantics is the study that aims to spell out a theoretical understanding of meaning. Most accounts of semantics insist that to spell out the meaning of a sentence is, in some sense, to spell out its truth-conditions. Now, *prima facie* at least, truth is a predicate characterised by the Tarski T-scheme:

$$T(\boldsymbol{A}) \leftrightarrow A,$$

where A is a sentence and $\boldsymbol{A}$ is its name. But given any standard means of self-reference, e.g., arithmetisation, one can construct a sentence, B, which means that $\sim T(\boldsymbol{B})$. The T-scheme gives that $T(\boldsymbol{B}) \leftrightarrow \sim T(\boldsymbol{B})$. It then follows that $T(\boldsymbol{B}) \;\&\; \sim T(\boldsymbol{B})$. (This is, of course, just the liar paradox.)

The situation is similar in set theory. The naive, and intuitively correct, axioms of set theory are the *Comprehension Schema* and *Extensionality Principle*:

$$(\exists y)(x)(x \in y \leftrightarrow A)$$

$$(x)(x \in y \leftrightarrow x \in z) \rightarrow y = z$$

where x does not occur free in A. As was discovered by Russell, any theory that contains the Comprehension Schema is inconsistent. For putting ‘$y \notin y$’ for A in the Comprehension Schema and instantiating the existential quantifier to an arbitrary such object ‘r’ gives:

$$(y)(y \in r \leftrightarrow y \notin y)$$

So, instantiating the universal quantifier to ‘r’ gives:

$$r \in r \leftrightarrow r \notin r$$

It then follows that $r \in r$ & $r \notin r$.

The standard approaches to these problems of inconsistency are, by and large, ones of expedience. However, a paraconsistent approach makes it possible to have theories of truth and sethood in which the fundamental intuitions about these notions are respected. The contradictions may be allowed to arise, but these need not infect the rest of the theory.

The Philosophical Significance of Gödel's Theorem

Paraconsistent logic also has important philosophical ramifications. One example of this concerns Gödel's theorem. One version of Gödel's first incompleteness theorem states that for any consistent axiomatic theory of arithmetic, which can be recognised to be sound, there will be an arithmetic truth - viz., its Gödel sentence - not provable in it, but which can be established as true by intuitively correct reasoning. The heart of Gödel's theorem is, in fact, a paradox that concerns the sentence, *G*, 'This sentence is not provable'. If *G* is provable, then it is true and so not provable. Thus *G* is proved. Hence *G* is true and so unprovable. If an underlying paraconsistent logic is used to formalise the arithmetic, and the theory therefore allowed to be inconsistent, the Gödel sentence may well be provable in the theory (essentially by the above reasoning). So a paraconsistent approach to arithmetic overcomes the limitations of arithmetic that are supposed (by many) to follow from Gödel's theorem.

Systems of Paraconsistent Logic

The foregoing discussion indicates some of the motivations for paraconsistent logic, its applications and implications. We will now indicate some of the main approaches to paraconsistency. There are many different paraconsistent logics. Most of them can be defined in terms of a semantics which allows both *A* and ~*A* to hold in an interpretation. Validity is then defined in terms of the preservation of holding in an interpretation, and so ECQ fails. We will illustrate this with four kinds of propositional paraconsistent logics: *non-adjunctive*, *non-truth-functional*, *many-valued*, and *relevant*. (Paraconsistent quantified logics are straightforward extensions of these.) In all the following systems, not only ECQ fails, but so does the Disjunctive Syllogism (DS), defined as the following inference rule: $\{A, {\sim}A \vee B\} \vdash B$. In particular, then, if one defines the material conditional, $A \supset B$, as ${\sim}A \vee B$ (as usual) then *modus ponens* for this fails.

- Non-Adjunctive Systems
- Non-Truth-Functional Logics
- Many-Valued Systems
- Relevant Logics

Non-Adjunctive Systems

Let us start with non-adjunctive systems, so called because the inference from *A* and *B* to *A & B* fails. The first of these to be produced was also the first formal paraconsistent logic. This was Jaskowski's *discussive* (or *discursive*) *logic*. In a discourse, each participant puts forward some information, beliefs, or opinions. What is true in a discourse is the sum of opinions given by participants. Each participant's opinions are taken to be self-consistent, but may be inconsistent with those of others. To formalise this idea, take an interpretation, *I*, to be one for a standard modal logic, say *S5*. Each participant's belief set is the set of sentences true in a possible world in *I*. Thus, *A* holds in *I* iff *A* holds at *some* world in *I*. Clearly, one may have both *A* and ~*A* (but not *A & ~A*) holding in an interpretation. Since *modus ponens* for ⊃ fails, Jaskowski introduced a connective he called discussive implication, $\supset_d$, defined as ($\Diamond A \supset B$). It is easy to check that in *S5* discussive implication satisfies *modus ponens*.

Non-Truth-Functional Logics

The study of non-truth-functional systems was initiated by da Costa (who has also produced several other kinds of system). The main idea here was to maintain the apparatus of some positive logic, say classical or intuitionistic, but to allow negation in an interpretation to behave non-truth-functionally. Thus, take an interpretation to be a function which maps formulas to 1 or 0; *&* , ∨, and → behave in the usual (classical) way, but the value of ~*A* is independent of that of *A*. In particular, both may take the value 1. Negation has no significant properties under these semantics. Various properties of negation may be obtained by adding further constraints on interpretations. If we add the requirements that, for any *A*, either *A* or ~*A* must take the value 1 (giving the Law of Excluded Middle) and that whenever ~~*A* takes the value 1, so does *A*, we obtain the core of da Costa's systems C_i , for finite *i*. If we start with an appropriate semantics for positive intuitionist logic, and proceed in the same way, we obtain da Costa's logic $C\omega$. If we write A^{o} for *~(A & ~A)* then it is natural to take it as expressing the consistency of *A*. Further postulates constraining how A^{o} behaves differentiate between the C_i systems for finite *i*.

Many-Valued Systems

Perhaps the simplest way of generating a paraconsistent logic, first proposed by Asenjo, is to use a many-valued logic, that is, a logic with more than two truth values. The formulas which hold in a many-valued interpretations are those which have a value said to be *designated*. A many-valued logic will therefore be paraconsistent if it allows both a formula and its negation to be designated. The simplest strategy is to use three truth values: *true (only)* and *false (only)*, which function as in classical logic, and *both truth and false* (which, naturally, is a fixed point for negation). Both varieties of truth are designated. This is the approach of the paraconsistent logic *LP*. If one adds a fourth value, *neither true nor false*, which behaves in an appropriate way, one obtains Dunn's semantics for First Degree Entailment. If one takes the truth values to be the real numbers between 0 and 1, with a suitable set of designated values, the logic will be a natural paraconsistent fuzzy logic.

Relevant Logics

Relevant logics were pioneered by Anderson and Belnap. World-semantics for them were developed by R. and V.Routley and Meyer. In an interpretation for such logics, conjunction and disjunction behave in the usual way. But each world, *w*, has an associate world, *w**; and ~*A* is true at *w* iff *A* is false, not at *w*, but *w**. Thus, if *A* is true at *w*, but false at *w**, *A* & ~*A* is true at *w*. To obtain the standard relevant logics, one needs to add the constraint that *w*** = *w*. As is clear, negation in these semantics is an intensional operator. (There are also versions of world-semantics for relevant logics based on Dunn's four-valued semantics. In these, negation is extensional.)

The concern with relevant logics is not so much with negation as with a conditional connective, → (satisfying *modus ponens*). Semantics for this are obtained by furnishing each interpretation with a *ternary* relation, *R*. In the simplified semantics of Priest, Sylvan and Restall, worlds are divided into normal and non-normal. If *w* is a normal world, *A* → *B* is true at *w* iff at all worlds where *A* is true, *B* is true. If *w* is non-normal, *A* → *B* is true at *w* iff for all *x*, *y*, such that *Rwxy*, if *A* is true at *x*, *B* is true at *y*. (Validity is defined as truth preservation over *normal* worlds.) This gives the basic relevant logic, *B*. Stronger logics, such as the logic *R*, are obtained by adding constraints on the ternary relation. Further details concerning relevant logics can be found in the article on that topic in this encyclopedia.

Relevance Logic

Relevance logics are non-classical logics. Called ‘relevance logics’ in North America and ‘relevant logics’ in Britain and Australasia, these systems developed as attempts to avoid the paradoxes of material and strict implication. Among the paradoxes of material implication are

- $p \rightarrow (q \rightarrow p)$.
- $\sim p \rightarrow (p \rightarrow q)$.
- $(p \rightarrow q) \vee (q \rightarrow r)$.

Among the paradoxes of strict implication are the following:

- $(p \,\&\, \sim p) \rightarrow q$.
- $p \rightarrow (q \rightarrow q)$.
- $p \rightarrow (q \vee \sim q)$.

Relevance logicians claim that what is unsettling about these so-called paradoxes is that in each of them the antecedent seems irrelevant to the consequent.

In addition, relevance logicians have had qualms about certain inferences that classical logic makes valid. For example, the inference

> The moon is made of green cheese. Therefore, either it is raining in Ecuador now or it is not.

Again here there seems to be a failure of relevance. The conclusion seems to have nothing to do with the premise. Relevance logicians have attempted to construct logics that reject theses and arguments that commit "fallacies of relevance".

At this point some confusion is natural about what relevant logicians have attempted to do. They have not given formal criteria of relevance that any true implication must meet, altough some relevant logicans have interpreted the semantics for relevance logic using informal notions of relevance (see the section "Semantics" below). Instead, relevant logic is relevant in two ways: (1) Relevance logics do not force us to accept any irrelevances. That is, they do not make valid any of the paradoxes. (2) Some relevance logics, through their proof theory, yield a relevant notion of proof (see the section "Proof Theory"

below).

In this article we will give a brief and relatively non-technical overview of the field of relevant logic.

Semantics

Our exposition of relevant logic is backwards to most found in the literature We will begin, rather than end, with the semantics, since most philosophers at present are semantically inclined.

The semantics that I present here is the ternary relation semantics due to Richard Routley and Robert K. Meyer. There are algebraic semantics due to J. Michael Dunn and Alasdair Urquhart and operational semantics produced by Kit Fine. These systems are interesting in their own right, but we do not have room to discuss them here.

The idea behind the ternary relation semantics is rather simple. Consider C.I. Lewis' attempt to avoid the paradoxes of material implication. He added a new connective to classical logic, that of strict implication. In post-Kripkean semantic terms, $A ⥽ B$ is true at a world w if and only if for all w' such that w' is accessible to w, either A fails in w' or B obtains there. Now, in Kripke's semantics for modal logic, the accessibility relation is a binary relation. It holds between pairs of worlds. Unfortunately, from a relevant point of view, the theory of strict implication is still irrelevant. That is, we still make valid formulae like $p ⥽ (q ⥽ q)$. We can see quite easily that the Kripke truth condition forces this formula on us.

Like the semantics of modal logic, the semantics of relevance logic relativises truth of formulae to worlds. But Routley and Meyer go modal logic one better and use a three-place relation on worlds. This allows there to be worlds at which $q \rightarrow q$ fails and that in turn allows worlds at which $p \rightarrow (q \rightarrow q)$ fails. Their truth condition for $\rightarrow$ on this semantics is the following:

> $A \rightarrow B$ is true at a world a if and only if for all worlds b and c such that $Rabc$ (R is the accessibility relation) either A is false at b or B is true at c.

For new customers, it takes some time to get used to this truth condition. But with a little work it can be seen to be just a generalisation of the Kanger-Kripke truth condition for strict implication (just set $b = c$).

But how should this accessibility relation be interpreted philosophically? Oddly, there has not been very much work on this, but there has been some. Mares (1997) uses a theory of information due to David Israel and John Perry (see Israel and Perry (1990)). On this interpreation, in addition to other information a world contains informational links, such as laws of nature, conventions, and so on. Thus, for example, a Newtonian world will contain the information that all matter attracts all other matter. In information-theoretic terms, this world contains the information that two things' being material carries the information that they attract each other. On this view, *Rabc* if and only if, according to the links in *a*, all the information carried by what obtains in *b* is contained in *c*. Thus, for example, if *a* is a Newtonian world and the information that *x* and *y* are material is contained in *b*, then the information that *x* and *y* attract each other is contained in *c*.

Another similar interpretation is given in Barwise (1993) and developed in Restall (1996). On this view, worlds are taken to be information-theoretic "sites". *Rabc* means that *a* is an information-theoretic channel between *b* and *c*. Both this channel-theoretic interpretation of the accessibiliity relation and the other information-theoretic interpretation attempt to provide the formal semantics with an informal notion of relevance. On these interpretations, what is needed for an implication to be true is that the antecedent carry the information that the consequent obtains. The antecedent must be informationally relevant to the consequent.

By itself, the ternary relation is not sufficient to avoid all the paradoxes of implication. Given what we have said so far, it is not clear how the semantics can avoid paradoxes such as $(p \,\&\, {\sim}p) \rightarrow q$ and $p \rightarrow (q \vee {\sim}q)$. These paradoxes are avoided by the inclusion of inconsistent and non-bivalent worlds in the semantics. For, if there were no worlds at which $p \,\&\, {\sim}p$ holds, then, according to our truth condition for the arrow, $(p \,\&\, {\sim}p) \rightarrow q$ would also hold everywhere. Likewise, if $q \vee {\sim}q$ held at every world, then $p \rightarrow (q \vee {\sim}q)$ would be universally true.

This brings us to the semantics for negation. The use of non-bivalent and inconsistent worlds requires a non-classical truth condition for negation. In the early 1970s, Richard and Val Routley invented their "star operator" to treat negation. The operator is an operator on worlds. For each world *a*, there is a world *a**. And

> ~*A* is true at *a* if and only if *A* is false at *a**.

Once again, we have the difficulty of interpreting a part of the formal semantics. What may be the nicest interpretation of the Routley star is that of Dunn (1993). Dunn uses a binary relation, *C*, on worlds. '*Cab*' means that *b* is compatable with *a*. *a**, then, is the maximal world (the world containing the most information) that is compatable with *a*.

There are other semantics for negation. One, due to Dunn and developed by Routley, is a four-valued

semantics. This semantics is treated in the entry on paraconsitent logics.

Proof Theory

There is now a lage variety of approaches to proof theory for relevant logics. There is a Gentzen system for the negation-free fragment of the logic **R** by J.M. Dunn and an elegant and very general Gentzen-style approach called "Display Logic" recently developed by Nuel Belnap. But here I will only deal with an treatment that most philosophers will find somewhat familiar, that is, the natural deduction system due to Anderson and Belnap.

Anderson and Belnap's natural deduction system is based on Fitch's natural deduction systems for classical and intuitionistic logic. The easiest way to understand this technique is by looking at an example.

1. $A_{\{1\}}$	hyp
2. $(A \rightarrow B)_{\{2\}}$	hyp
3. $B_{\{1,2\}}$	1,2, $\rightarrow$E
4. $((A \rightarrow B) \rightarrow B)_{\{1\}}$	2,3, $\rightarrow$I
5. $A \rightarrow ((A \rightarrow B) \rightarrow B)$	1,4, $\rightarrow$I

The numbers in set brackets indicate the assuptions used to prove the formula. We will call them ‘indices’. The idea here is that for an assumption to be counted as helping to generate the conclusion, an index denoting the assumption must be appear in the deduction and at some later point be discharged. This ensures that each premise is really used in the deduction. This natural deduction system gives an intuitive understanding of relevance in proofs. The indices keep track of which assumptions are used. For an argument to be valid in this system, all assumptions stated must really be used.

Now, it might seem that the system of indices allows irrelevant premises to creep in. One way in which it might appear that irrelevances can intrude is through the use of a rule of conjunction introduction. That is, it might seem that we can always add in an irrelevant premise by doing, say, the following:

1. $A_{\{1\}}$	hyp
2. $B_{\{2\}}$	hyp
3. $(A \& B)_{\{1,2\}}$	1,2, &I
4. $B_{\{1,2\}}$	3, &E
5. $(B \rightarrow B)_{\{1\}}$	2,4, $\rightarrow$I

6. $A \rightarrow (B \rightarrow B)$	1,5, $\rightarrow$I

To a relevance logician, the first premise is completely out of place here. To block moves like this, Anderson and Belnap give the following conjunction introduction rule:

From A_i and B_i to infer $(A \& B)_i$.

This rule says that two formulae must have the same index before the rule of conjunction introduction can be used.

There is, of course, a lot more to the natural deduction system, but this will suffice as for our current purposes. The theory of relevance that is captured by at least some relevant logics can be understood by how the corresponding natural deduction system understands a real use of a premise and how the rules are allowed to access premises.

Systems of Relevance Logic

Historically, the central systems of relevance logic have been the logic **E** of entailment and the system **R** or relevant implication. **E** was supposed to capture strict relevant implication. But, when a necessity operator and the appropriate modal axioms were added to **R** (to produce the logic **NR**), it was discovered that the resulting modal system was different from **E**. This has left some relevant logicians with a quandary. They have to decide whether to take **NR** to be the system of strict relevant implication, or to claim that **NR** was somehow defficient and that **E** stands as the system of strict relevant implication.

On the other hand, there are those relevance logicians who reject both **R** and **E**. On one hand there is Arnon Avron who has used semantic arguments to motivate logics stronger than **R**. On the other hand there are logicians like Ross Brady, John Slaney, Steve Giabrione, Richard Sylvan, Graham Priest and Greg Restall who have argued for the acceptance of systems weaker than **R** or **E**. Among the points in favour of weaker these systems is that, unlike **R** or **E**, many of them are decidable.

On an extreme end of the spectrum is the logic **S** of R.K. Meyer, Errol Martin and Robin Dwyer. This logic contains no theorems of the form $A \rightarrow A$. In other words, according to **S**, no proposition implies itself and no argument of the form '*A*, therefore *A*' is valid. Thus, this logic does not make valid any circular arguments.

Applications of Relevance Logic

Apart from the motivating applications of providing better formalisms of our pre-formal notions of implication and entailment, relevance logic has been put to various uses in philosophy and computer science. Here I will list just a few.

Dunn has developed a theory of intrinsic and essential properties based on relevant logic. This is his theory of *relevant predication*. Briefly put, a thing i has a property F relevantly if $\forall x(x=i \rightarrow F(x))$. Informally, an object has a property relevantly if being that thing relevantly implies having that property. Since the truth of the consequent of a relevant implication is by itself insufficient for the truth of that implication, things can have properties irrelevantly as well as relevantly. Dunn's formulation would seem to capture at least one sense in which we use the notion of an intrisic property. Adding modality to the language allows for a formilisation of the notion of an essential property.

Meyer has produced a variant of Peano arithmetic based on the relevance logic, **R**. Meyer gives a finitary proof that his relevant arithmetic does not have 0 = 1 as a theorem. Thus Meyer solves one of Hilbert's central problems in the context of relevant arithmetic: He shows using finitary means that relevant arithmetic is absolutely consistent. Unfortunately, as Meyer and Friedman have shown, relevant arithmetic does not contain all of the theorems of classical Peano arithmetic. Hence we cannot infer from this that classical Peano arithmetic is absolutely consistent (see Meyer and Friedman (1992)).

In a similar vein, Ross Brady and others have used weak relevant logics as bases for set theories. Brady shows that a weak relevant logic together with some set-theoretic axioms that include a naive comprehension principle is not trivial. That is, not every proposition can be proved in this system.

Anderson (1967) formulates a system of deontic logic based on **R**. This system avoids some of the standard problems with more traditional deontic logics. For example, the rule of necessitation from *A*'s being a theorem to *OA*'s being a theorem is rejected. Thus, it does not say that all theorems ought to be the case.

Mares and Fuhrmann (1995) present a theory of counterfactual conditionals based on relevant logic. This theory avoids the analogs of the paradoxes of implication that appear in standard logics of counterfactuals.

Relevant logics have been used in computer science as well as in philosophy. Linear logics, a branch of logic discoverd by the French logician Girard, is a logic of computational resources. Linear logic is, in fact, a weak relevant logic with the addition of two operators.

Bibliography

An extremely good, although slightly out of date, bibliography on relevance logic was put together by Robert Wolff and is in Anderson, Belnap and Dunn (1992). What follows is a brief list of some of the more influential works in the field and works that are referred to above.

Books on Relevance Logic and Introductions to the Field:

- Anderson, A.R. and N.D. Belnap, Jr. (1975) *Entailment: The Logic of Relevance and Necessity*, Princeton, Princeton University Press, Volume I. Anderson, A.R. N.D. Belnap, Jr. and J.M. Dunn (1992) *Entailment*, Volume II. [These are both collections of slightly modified articles on relevance logic together with a lot of material unique to these volumes. Excellent work and still the standard books on the subject. But they are very technical and quite difficult.]
- Read, S. (1988), *Relevant Logic*, Oxford: Blackwell. [A very interesting and fun book. Idiosyncratic, but philosophically adept and excellent on the pre-history and early history of relevance logic.]
- Routley, R., R.K. Meyer, V. Plumwood and R. Brady (1983), *Relevant Logics and its Rivals*, Volume I, Atascardero, CA: Ridgeview. [A very useful book for formal results especially about the semantics of relevance logics. The introduction and philosophical remarks are full of "Richard Routleyisms". They tend to be Routley's views rather than the views of the other authors and are fairly radical even for relevant logicians. Volume II is currently in the works. It is a large editorial project headed by Ross Brady.]
- Dunn, J.M. (1986) "Relevance Logic and Entailment" in F. Guenthner and D. Gabbay (eds.), *Handbook of Philosophical Logic*, Volume 3, Dordrecht: Reidel pp 117--224. [The best long introduction to relevance logic currently published. Dunn and Restall are currently rewriting this chapter for the next edition of the *Handbook*.]

Modal Logic

A modal is an expression (like 'necessarily' or 'possibly') that is used to qualify the truth of a judgement. Modal logic is, strictly speaking, the study of the deductive behavior of the expressions 'it is necessary that' and 'it is possible that'. However, the term 'modal logic' may be used more broadly for a family of related systems. These include logics for belief, for tense and other temporal expressions, for the deontic (moral) expressions such as 'it is obligatory that' and 'it is permitted that', and many others. An understanding of modal logic is particularly valuable in the formal analysis of philosophical argument, where expressions from the modal family are both common and confusing. Modal logic also has important applications in computer science.

1. What is Modal Logic?

Narrowly construed, modal logic studies reasoning that involves the use of the expressions 'necessarily' and 'possibly'. However, the term 'modal logic' is used more broadly to cover a family of logics with similar rules and a variety of different symbols.

A list describing the best known of these logics follows.

Logic	Symbols	Expressions Symbolized
Modal Logic	$\Box$	It is necessary that ..
	$\Diamond$	It is possible that ..
Deontic Logic	O	It is obligatory that ..
	P	It is permitted that ..
	F	It is forbidden that ..
Temporal Logic	G	It will always be the case that ..
	F	It will be the case that ..
	H	It has always been the case that ..
	P	It was the case that..
Doxastic Logic	Bx	x believes that ..

2. Modal Logics

The most familiar logics in the modal family are constructed from a weak logic called K (after Saul Kripke). Under the narrow reading, modal logic concerns necessity and possibility. A variety of different systems may be developed for such logics using K as a foundation. The symbols of K include '~' for 'not', '$\rightarrow$' for 'if...then', and '$\Box$' for the modal operator 'it is necessary that'. (The connectives '&', '$\vee$', and '$\leftrightarrow$' may be defined from '~' and '$\rightarrow$' as is done in propositional logic.) K results from adding the following to the principles of propositional logic.

Necessitation Rule: If A is a theorem of K, then so is $\Box$A.

Distribution Axiom: $\Box(A\rightarrow B) \rightarrow (\Box A\rightarrow\Box B)$.

(In these principles we use 'A' and 'B' as metavariables ranging over formulas of the language.) According to the Necessitation Rule, any theorem of logic is necessary. The Distribution Axiom says that if it is necessary that if A then B, then if necessarily A then necessarily B.

The operator $\Diamond$ (for 'possibly') can be defined from $\Box$ by letting $\Diamond A = {\sim}\Box{\sim}A$. In K, the operators $\Box$ and $\Diamond$ behave very much like the quantifiers $\forall$ (all) and $\exists$ (some). For example, the definition of $\Diamond$ from $\Box$ mirrors the equivalence of $\forall xA$ with ${\sim}\exists x{\sim}A$ in predicate logic. Furthermore, $\Box(A\&B)$ entails $\Box A\&\Box B$ and vice versa; while $\Box A\vee\Box B$ entails $\Box(A\vee B)$, but *not* vice versa. This reflects the patterns exhibited by the universal quantifier: $\forall x(A\&B)$ entails $\forall xA\&\forall xB$ and vice versa, while $\forall xA\vee\forall xB$ entails $\forall x(A\vee B)$ but not vice versa. Similar parallels between $\Diamond$ and $\exists$ can be drawn. The basis for this correspondence

between the modal operators and the quantifiers will emerge more clearly in the section on Possible Worlds Semantics.

The system K is too weak to provide an adequate account of necessity. The following axiom is not provable in K, but it is clearly desirable.

(M) $\Box A \rightarrow A$

(M) claims that whatever is necessary is the case. Notice that (M) would be incorrect were $\Box$ to be read 'it ought to be that', or 'it was the case that'. So the presence of axiom (M) distinguishes modal from other logics in the modal family. A basic modal logic M results from adding (M) to K. (Some authors call this system T.)

Many logicians believe that M is still too weak to correctly formalize the logic of necessity and possibility. They recommend further axioms to govern the iteration, or repetition of modal operators. Here are two of the most famous iteration axioms:

(4) $\Box A \rightarrow \Box\Box A$

(5) $\Diamond A \rightarrow \Box\Diamond A$

S4 is the system that results from adding (4) to M. Similarly S5 is M plus (5). In S4, the sentence $\Box\Box A$ is equivalent to $\Box A$. As a result, any string of boxes may be replaced by a single box, and the same goes for strings of diamonds. This amounts to the idea that iteration of the modal operators is superfluous. Saying that A is necessarily necessary is considered a uselessly long-winded way of saying that A is necessary. The system S5 has even stronger principles for simplifying strings of modal operators. In S4, a string of operators of *the same kind* can be replaced for that operator; in S5, strings containing both boxes and diamonds are equivalent to the last operator in the string. So, for example, saying that it is possible that A is necessary is the same as saying that A is necessary. A summary of these features of S4 and S5 follows.

S4: $\Box\Box...\Box = \Box$ and $\Diamond\Diamond...\Diamond = \Diamond$

S5: $00...\Box = \Box$ and $00...\Diamond = \Diamond$, where each 0 is either $\Box$ or $\Diamond$

One could engage in endless argument over the correctness or incorrectness of these and other iteration principles for $\Box$ and $\Diamond$. The controversy can be partly resolved by recognizing that the words 'necessarily' and 'possibly', have many different uses. So the acceptability of axioms for modal logic depends on which of these uses we have in mind. For this reason, there is no one modal logic, but rather a whole family of systems built around M. The relationship between these systems is diagrammed in Section 8, and their application to different uses of 'necessarily' and 'possibly' can be more deeply understood by studying their possible world semantics in Section 6.

The system B (for the logician Brouwer) is formed by adding axiom (B) to M.

(B) $A \rightarrow \Box\Diamond A$

It is interesting to note that S5 can be formulated equivalently by adding (B) to S4. The axiom (B) raises an important point about the interpretation of modal formulas. (B) says that if A is the case, then A is necessarily possible. One might argue that (B) should always be adopted in any modal logic, for surely if A is the case, then it is necessary that A is possible. However, there is a problem with this claim that can be exposed by noting that $\Diamond\Box A \rightarrow A$ is provable from (B). So $\Diamond\Box A \rightarrow A$ should be acceptable if (B) is. However, $\Diamond\Box A \rightarrow A$ says that if A is possibly necessary, then A is the case, and this is far from obvious. Why does (B) seem obvious, while one of the things it entails seems not obvious at all? The answer is that there is a dangerous ambiguity in the English interpretation of $A \rightarrow \Box\Diamond A$. We often use the expression ‘If A then necessarily B’ to express that the conditional ‘if A then B’ is necessary. This interpretation corresponds to $\Box(A \rightarrow B)$. On other occasions, we mean that if A, then B is necessary: $A \rightarrow \Box B$. In English, ‘necessarily’ is an adverb, and since adverbs are usually placed near verbs, we have no natural way to indicate whether the modal operator applies to the whole conditional, or to its consequent. For these reasons, there is a tendency to confuse (B): $A \rightarrow \Box\Diamond A$ with $\Box(A \rightarrow \Diamond A)$. But $\Box(A \rightarrow \Diamond A)$ is not the same as (B), for $\Box(A \rightarrow \Diamond A)$ is already a theorem of M, and (B) is not. One must take special care that our positive reaction to $\Box(A \rightarrow \Diamond A)$ does not infect our evaluation of (B). One simple way to protect ourselves is to formulate B in an equivalent way using the axiom: $\Diamond\Box A \rightarrow A$, where these ambiguities of scope do not arise.

3. Deontic Logics

Deontic logics introduce the primitive symbol O for ‘it is obligatory that’, from which symbols P for ‘it is permitted that’ and F for ‘it is forbidden that’ are defined: PA = ~O~A and FA = O~A. The deontic analog of the modal axiom (M): $OA \rightarrow A$ is clearly not appropriate for deontic logic. (Unfortunately, what ought to be is not always the case.) However, a basic system D of deontic logic can be constructed by adding the weaker axiom (D) to K.

(D) $OA \rightarrow PA$

Axiom (D) guarantees the consistency of the system of obligations by insisting that when A is obligatory, A is permissible. A system which obligates us to bring about A, but doesn't permit us to do so, puts us in an inescapable bind. Although some will argue that such conflicts of obligation are at least possible, most deontic logicians accept (D).

$O(OA \rightarrow A)$ is another deontic axiom that seems desirable. Although it is wrong to say that if A is obligatory then A is the case ($OA \rightarrow A$), still, this conditional *ought* to be the case. So some deontic logicians believe that D needs to be supplemented with $O(OA \rightarrow A)$ as well.

Controversy about iteration (repetition) of operators arises again in deontic logic. In some conceptions of obligation, OOA just amounts to OA. ‘It ought to be that it ought to be’ is treated as a sort of stuttering; the extra ‘ought’s do not add anything new. So axioms are added to guarantee the equivalence of OOA and OA. The more general iteration policy embodied in S5 may also be adopted. However, there are conceptions of obligation where distinction between OA and OOA is preserved. The idea is that there are genuine differences between the obligations we *actually* have and the obligations we *should* adopt. So, for example, ‘it ought to be that it ought to be that A’ commands adoption of some obligation which may not actually be in place, with the result that OOA can be true even when OA is false.

4. Temporal Logics

In temporal logic (also known as tense logic), there are two basic operators, G for the future, and H for the past. G is read ‘it always will be that’ and the defined operator F (read ‘it will be the case that’), can be introduced by FA = ~G~A. Similarly H is read: ‘it always was that’ and P (for ‘it was the case that’) is defined by PA=~H~A. A basic system of temporal logic called Kt results from adopting the principles of K for both G and H, along with two axioms to govern the interaction between the past and future operators:

> "Necessitation" Rules: If A is a theorem then so are GA and HA.
>
> Distribution Axioms: G(A→B) → (GA→GB) and H(A→B) → (HA→HB)
>
> Interaction Axioms: A→GPA and A→HFA

The interaction axioms raise questions concerning asymmetries between the past and the future. A standard intuition is that the past is fixed, while the future is still open. The first interaction axiom (A →GPA) conforms to this intuition in reporting that what is the case (A), will at all future times, be in the past (GPA). However A→HFA may appear to have unacceptably deterministic overtones, for it claims, apparently, that what is true now (A) has always been such that it will occur in the future (HFA). However, possible world semantics for temporal logic reveals that this worry results from a simple confusion, and that the two interaction axioms are equally acceptable.

Note that the characteristic axiom of modal logic, (M): □A→A, is not acceptable for either H or G, since A does not follow from ‘it always was the case that A’, nor from ‘it always will be the case that A’. However, it is acceptable in a closely related temporal logic where G is read ‘it is and always will be’, and H is read ‘it is and always was’.

Depending on which assumptions one makes about the structure of time, further axioms must be added to temporal logics. A list of axioms commonly adopted in temporal logics follows. An account of how they depend on the structure of time will be found in the section Possible Worlds Semantics.

GA→GGA and HA→HHA

GGA→GA and HHA→HA

GA→FA and HA→PA

It is interesting to note that certain combinations of past tense and futuere tense operators may be used to express complex tenses in English. For example, FPA, corresponds to sentence A in the future perfect tense, (as in ‘20 seconds from now the light will have changed’). Similarly, PPA expresses the past perfect tense.

For a more detailed discussion of temporal logic, see the entry on temporal logic.

5. Conditional Logics

The founder of modal logic, C. I. Lewis, defined a series of modal logics which did not have □ as a primitive symbol. Lewis was concerned to develop of logic of conditionals that was free of the so called Paradoxes of Material Implication, namely the classical theorems A→(~A→B) and B→(A→B). He introduced the symbol ⥽ for "strict implication" and developed logics where neither A⥽(~A⥽B) nor B ⥽(A⥽B) is provable. The modern practice has been to define A⥽B by □(A→B), and use modal logics governing □ to obtain similar results. However, the provability of such formulas as (A&~A)⥽B in such logics seems at odds with concern for the paradoxes. Anderson and Belnap (1975) have developed systems R (for Relevance Logic) and E (for Entailment) which are designed to overcome such difficulties. These systems require revision of the standard systems of propositional logic. (For a more detailed discussion of relevance logic, see the entry on relevance logic.)

David Lewis (1973) has developed special conditional logics to handle counterfactual expressions, that is, expressions of the form ‘if A *were* to happen then B *would* happen’. (Kvart (1980) is another good source on the topic.) Counterfactual logics differ from those based on strict implication because the former reject while the latter accept contraposition.

6. Possible Worlds Semantics

The purpose of logic is to characterize the difference between valid and invalid arguments. A logical system for a language is a set of axioms and rules designed to prove *exactly* the valid arguments statable in the language. Creating such a logic may be a difficult task. The logican must make sure that the system is *sound*, i.e. that every argument proven using the rules and axioms is in fact valid. Furthermore, the system should be *complete*, meaning that every valid argument has a proof in the system. Demonstrating soundness and completeness of formal systems is a logician's central concern.

Such a demonstration cannot get underway until the concept of validity is defined rigorously. Formal semantics for a logic provides a definition of validity by characterizing the truth behavior of the sentences of the system. In propositional logic, validity can be defined using truth tables. A valid argument is simply one where every truth table row that makes its premises true also makes its conclusion true. However truth tables cannot be used to provide an account of validity in modal logics because there are no truth tables for expressions such as ‘it is necessary that’, ‘it is obligatory that’, and the like. (The problem is that the truth value of A does not determine the truth value for □A. For example, when A is ‘Dogs are dogs’, □A is true, but when A is ‘Dogs are pets’, □A is false. Nevertheless, semantics for modal logics can be defined by introducing possible worlds. We will illustrate possible worlds semantics for a logic of necessity containing the symbols ~, →, and □. Then we will explain how the same strategy may be adapted to other logics in the modal family.

In propositional logic, a valuation of the atomic sentences (or row of a truth table) assigns a truth value (T or F) to each propositional variable p. Then the truth values of the complex sentences is calculated with truth tables. In modal semantics, a set W of possible worlds is introduced. A valuation then gives a truth value to each propositional variable *for each of the possible worlds* in W. This means that value assigned to p for world w may differ from the value assigned to p for another world w′.

The truth value of the atomic sentence p at world w given by the valuation v may be written v(p, w). Given this notation, the truth values (T for true, F for false) of complex sentences of modal logic for a given valuation v (and member w of the set of worlds W) may be defined by the following truth clauses. (‘iff’ abbreviates ‘if and only if’.)

(~) v(~A, w)=T iff v(A, w)=F.

(→) v(A→B, w)=T iff v(A, w)=F or v(B, w)=T.

(5) v(□A, w)=T iff for every world w′ in W, v(A, w′)=T.

Clauses (~) and (→) simply describe the standard truth table behavior for negation and material implication respectively. According to (5), □A is true (at a world w) exactly when A is true in *all* possible worlds. Given the definition of ◇, (namely, ◇A = ~□~A) the truth condition (5) insures that ◇A is true just in case A is true in *some* possible world. Since the truth clauses for □ and ◇ involve the quantifiers ‘all’ and ‘some’ (respectively), the parallels in logical behavior between □ and ∀x, and between ◇ and ∃x noted in section 2 will be expected.

Clauses (~), (→), and (5) allow us to calculate the truth value of any sentence at any world on a given valuation. A definition of validity is now just around the corner. An argument is *5-valid for a given set W* (of possible worlds) if and only if every valuation of the atomic sentences that assigns the premises T at a world in W also assigns the conclusion T at the same world. An argument is said to be *5-valid* iff it is valid for every non empty set of W of possible worlds.

It has been shown that S5 is sound and complete for 5-validity (hence our use of the symbol ‘5’). The 5-valid arguments are exactly the arguments provable in S5. This result suggests that S5 is the correct way to formulate a logic of necessity.

However, S5 is not a reasonable logic for all members of the modal family. In deontic logic, temporal logic, and others, the analog of the truth condition (5) is clearly not appropriate; furthermore there are even conceptions of necessity where (5) should be rejected as well. The point is easiest to see in the case of temporal logic. Here, the members of W are moments of time, or worlds "frozen", as it were, at an instant. For simplicity let us consider a *future* temporal logic, a logic where □A reads: ‘it *will* always be the case that’. (We formulate the system using □ rather than the traditional G so that the connections with other modal logics will be easier to appreciate.) The correct clause for □ should say that □A is true at time w iff A is true at all times *in the future of w*. To restrict attention to the future, the relation R (for ‘eaRlier than’) needs to be introduced. Then the correct clause can be formulated as follows.

(K) v(□A, w)=T iff for every w′, if wRw′, then v(A, w′)=T.

This says that □A is true at w just in case A is true at all times *after* w.

Validity for this brand of temporal logic can now be defined. A *frame* <W, R> is a pair consisting of a non-empty set W (of worlds) and a binary relation R on W. A *model* <F, v> consists of a frame F, and a valuation v that assigns truth values to each atomic sentence at each world in W. Given a model, the values of all complex sentences can be determined using (~), (→), and (K). An argument is K-valid just in case any model whose valuation assigns the premises T at a world also assigns the conclusion T at the same world. As the reader may have guessed from our use of ‘K’, it has been shown that the simplest modal logic K is both sound and complete for K-validity.

7. Modal Axioms and Conditions on Frames

One might assume from this discussion that K is the correct logic when □ is read ‘it will always be the case that’. However, there are reasons for thinking that K is too weak. One obvious logical feature of the relation R (earlier than) is transitivity. If wRv (w is earlier than v) and vRu (v is earlier than u), then it follows that wRu (w is earlier than u). So let us define a new kind of validity that corresponds to this condition on R. Let a 4-model be any model whose frame <W, R> is such that R is a transitive relation on W. Then an argument is 4-valid iff any 4-model whose valuation assigns T to the premises at a world also assigns T to the conclusion at the same world. We use ‘4’ to describe such a transitive model because the logic which is adequate (both sound and complete) for 4-validity is K4, the logic which results from adding the axiom (4): □A→□□A to K.

Transitivity is not the only property which we might want to require of the frame <W, R> if R is to be read ‘earlier than’ and W is a set of moments. One condition (which is only mildly controversial) is that there is no last moment of time, i.e. that for every world w there is some world v such that wRv. This condition on frames is called *seriality*. Seriality corresponds to the axiom (D): □A→◇A, in the same

way that transitivity corresponds to (4). A D-model is a K-model with a serial frame. From the concept of a D-model the corresponding notion of D-validity can be defined just as we did in the case of 4-validity. As you probably guessed, the system that is adequate with respect to D-validity is KD, or K plus (D). Not only that, but the system KD4 (that is K plus (4) and (D)) is adequate with respect to D4-validity, where a D4-model is one where <W, R> is *both* serial and transitive.

Another property which we might want for the relation ‘earlier than’ is density, the condition which says that between any two times we can always find another. Density would be false if time were atomic, i.e. if there were intervals of time which could not be broken down into any smaller parts. Density corresponds to the axiom (C4): $\Box\Box A \rightarrow \Box A$, the converse of (4), so for example, the system KC4, which is K plus (C4) is adequate with respect to models where the frame <W, R> is dense, and KDC4, adequate with respect to models whose frames are serial and dense, and so on.

Each of the modal logic axioms we have discussed corresponds to a condition on frames in the same way. The relationship between conditions on frames and corresponding axioms is one of the central topics in the study of modal logics. Once an interpretation of the intensional operator □ has been decided on, the appropriate conditions on R can be determined to fix the corresponding notion of validity. This, in turn, allows us to select the right set of axioms for that logic.

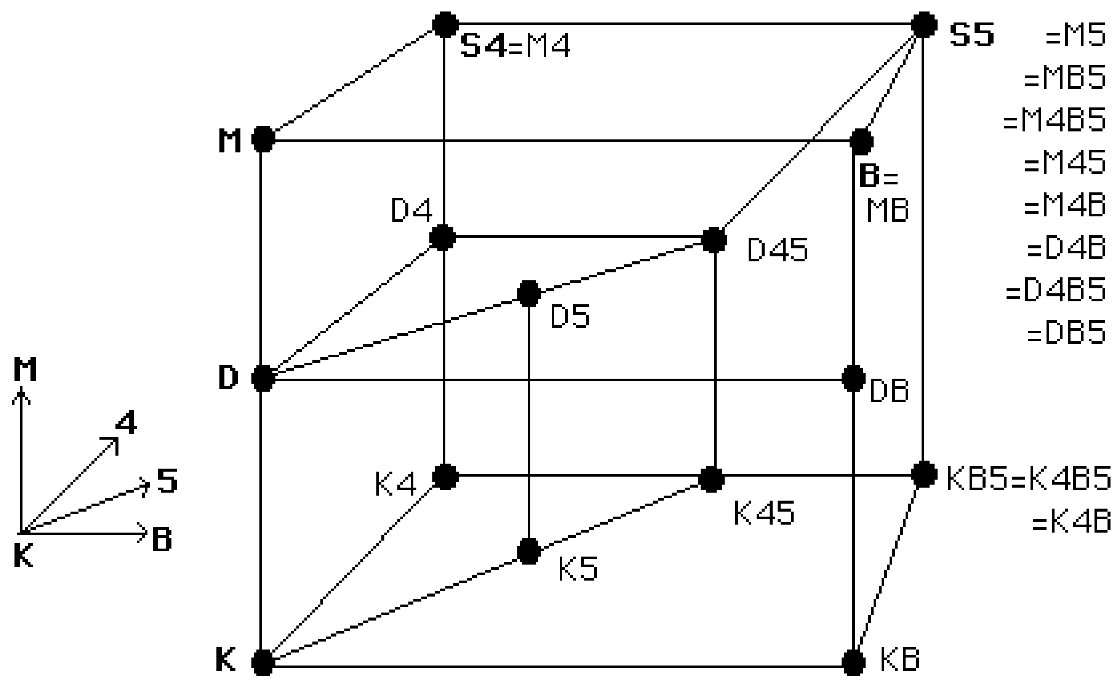
For example, consider a deontic logic, where □ is read ‘it is obligatory that’. Here the truth of □A does not demand the truth of A in *every* possible world, but only in a subset of those worlds where people do what they ought. So we will want to introduce a relation R for for this kind of logic as well, and use the truth clause (K) to evaluate □A at a world. However, in this case, R is not earlier than. Instead wRw' holds just in case world w' is a morally acceptable variant of w, i.e. a world that our actions can bring about which satisfies what is morally correct, or right, or just. Under such a reading, it should be clear that the relevant frames should obey seriality, the condition that requires that each possible world have a morally acceptable variant. The analysis of the properties desired for R makes it clear that a basic deontic logic can be formulated by adding the axiom (D) and to K.

Even in modal logic, one may wish to restrict the range of possible worlds which are relevant in determining whether □A is true at a given world. For example, I might say that it is necessary for me to pay my bills, even though I know full well that there is a possible world where I fail to pay them. In ordinary speech, the claim that A is necessary does not require the truth of A in *all* possible worlds, but rather only in a certain class of worlds which I have in mind (for example, worlds where I avoid penalties for failure to pay). In order to provide a generic treatment of necessity, we must say that □A is true in w iff A is true in all worlds *that are related* to w in the right way. So for an operator □ interpreted as necessity, we introduce a corresponding relation R on the set of possible worlds W, traditionally called the accessibility relation. The accessibility relation R holds between worlds w and w' iff w' is possible given the facts of w. Under this reading for R, it should be clear that frames for modal logic should be reflexive. It follows that modal logics should be founded on M, the system that results from adding (M) to K. Depending on exactly how the accessibility relation is understood, symmetry and transitivity may also be desired.

A list of some of the more commonly discussed conditions on frames and their corresponding axioms along with a map showing the relationship between the various modal logics can be found in the next section.

8. Map of the Relationships Between Modal Logics

The following diagram shows the relationships between the best known modal logics, namely logics that can be formed by adding a selection of the axioms (D), (M), (4), (B) and (5) to K. A list of these (and other) axioms along with their corresponding frame conditions can be found below the diagram.



In this chart, systems are given by the list of their axioms. So, for example M4B is the result of adding (M) (4) and (B) to K. In boldface, we have indicated traditional names of some systems. When system S appears below and/or to the left of S′ connected by a line, then S′ is an extension of S. This means that every argument provable in S is provable in S′, but S is weaker than S′, i.e. not all arguments provable in S′ are provable in S.

The following list indicates axioms, their names, and the corresponding conditions on the accessibility relation R, for axioms so far discussed in this encyclopedia entry.

Axiom Name	Axiom	Condition on Frames	R is...
(D)	$\Box A \rightarrow \Diamond A$	$\exists u\ wRu$	Serial
(M)	$\Box A \rightarrow A$	wRw	Reflexive

(4)	$\Box A \rightarrow \Box\Box A$	(wRv&vRu) $\Rightarrow$ wRu	Transitive
(B)	$A \rightarrow \Box\Diamond A$	wRv $\Rightarrow$ vRw	Symmetric
(5)	$\Diamond A \rightarrow \Box\Diamond A$	(wRv&wRu) $\Rightarrow$ vRu	Euclidean
(CD)	$\Diamond A \rightarrow \Box A$	(wRv&wRu) $\Rightarrow$ v=u	Unique
($\Box$M)	$\Box(\Box A \rightarrow A)$	wRv $\Rightarrow$ vRv	Shift Reflexive
(C4)	$\Box\Box A \rightarrow \Box A$	wRv $\Rightarrow$ ∃u(wRu&uRv)	Dense
(C)	$\Diamond\Box A \rightarrow \Box\Diamond A$	wRv&wRx $\Rightarrow$ ∃u(vRu&xRu)	Convergent

In the list of conditions on frames, the variables ‘w’, ‘v’, ‘u’, ‘x’ and the quantifier ‘∃u’ are understood to range over W. ‘&’ abbreviates ‘and’ and ‘ $\Rightarrow$ ’ abbreviates ‘if...then’.

9. The General Axiom

The correspondence between axioms and conditions on frames may seem something of a mystery. A beautiful result of Lemmon and Scott (1977) goes a long way towards explaining those relationships. Their theorem concerned axioms which have the following form:

(G) $\Diamond^h\Box^i A \rightarrow \Box^j\Diamond^k A$

We use the notation ‘$\Diamond^n$’ to represent n diamonds in a row, so, for example, ‘$\Diamond^3$’ abbreviates a string of three diamonds: ‘$\Diamond\Diamond\Diamond$’. Similarly ‘$\Box^n$’ represents a string of n boxes. When the values of h, i, j, and k are all 1, we have axiom (C):

(C) $\Diamond\Box A \rightarrow \Box\Diamond A \;=\; \Diamond^1\Box^1 A \rightarrow \Box^1\Diamond^1 A$

The axiom (B) results from setting h and k to 0, and letting j and k be 1:

(B) $A \rightarrow \Box\Diamond A \;=\; \Diamond^0\Box^0 A \rightarrow \Box^1\Diamond^1 A$

To obtain (4), we may set h and k to 0, set i to 1 and j to 2:

(4) $\Box A \rightarrow \Box\Box A \;=\; \Diamond^0\Box^1 A \rightarrow \Box^2\Diamond^0 A$

Many (but not all) axioms of modal logic can be obtained by setting the right values for the parameters in (G)

Our next task will be to give the condition on frames which corresponds to (G) for a given selection of values for h, i, j, and k. In order to do so, we will need a definition. The composition of two relations R and R′ is a new relation R∘R′ which is defined as follows:

$wR \circ R'v$ iff for some u, wRu and uR′v.

For example, if R is the relation of being a brother, and R′ is the relation of being a parent then R∘R′ is the relation of being an uncle, (because w is the uncle of v iff for some person u, both w is the brother of u and u is the parent of v). A relation may be composed with itself. For example, when R is the relation of being a parent, then R∘R is the relation of being a grandparent, and R∘R∘R is the relation of being a great-grandparent. It will be useful to write 'R^n', for the result of composing R with itself n times. So R^2 is R∘R, and R^4 is R∘R∘R∘R. We will let R^1 be R, and R^0 will be the identity relation, i.e. wR^0v iff w=v.

We may now state the Scott-Lemmon result. It is that the condition on frames which corresponds exactly to any axiom of the shape (G) is the following.

(hijk-Convergence) $wR^hv \ \& \ wR^ju \Rightarrow \exists x \ (vR^ix \ \& \ uR^kx)$

It is interesting to see how the familiar conditions on R result from setting the values for h, i, j, and k according to the values in the corresponding axiom. For example, consider (5). In this case i=0, and h=j=k=1. So the corresponding condition is

$wRv \ \& \ wRu \Rightarrow \exists x \ (vR^0x \ \& \ uRx).$

We have explained that R^0 is the identity relation. So if vR^0x then v=x. But ∃x (v=x & uRx), is equivalent to uRv, and so the Euclidean condition is obtained:

$(wRv \ \& \ wRu) \Rightarrow uRv.$

In the case of axiom (4), h=0, i=1, j=2 and k=0. So the corresponding condition on frames is

$(w=v \ \& \ wR^2u) \Rightarrow \exists x \ (vRx \ \& \ u=x).$

Resolving the identities this amounts to:

$vR^2u \Rightarrow vRu.$

By the definition of R^2, vR^2u iff ∃x(vRx & xRu), so this comes to:

$\exists x(vRx \ \& \ xRu) \Rightarrow vRu,$

which by predicate logic, is equivalent to transitivity.

$vRx \ \& \ xRu \Rightarrow vRu.$

The reader may find it a pleasant exercise to see how the corresponding conditions fall out of hijk-Convergence when the values of the parameters h, i, j, and k are set by other axioms.

The Scott-Lemmon results provides a quick method for establishing results about the relationship between axioms and their corresponding frame conditions. Since they showed the adequacy of any logic that extends K with a selection of axioms of the form (G) with respect to models that satisfy the corresponding set of frame conditions, they provided "wholesale" adequacy proofs for the majority of systems in the modal family. Sahlqvist (1975) has discovered important generalizations of the Scott-Lemmon result covering a much wider range of axiom types.

10. Provability Logics

Modal logic has been useful in clarifying our understanding of central results concerning provability in the foundations of mathematics (Boolos, 1993). Provability logics are systems where the propositional variables p, q, r, etc. range over formulas of some mathematical system, for example Peano's system PA for arithmetic. (The system chosen for mathematics might vary, but assume it is PA for this discussion.) Gödel showed that arithmetic has strong expressive powers. Using code numbers for arithmetic sentences, he was able to demonstrate a correspondence between sentences of mathematics and facts about which sentences are and are not provable in PA. For example, he showed there there is a sentence C that is true just in case no contradiction is provable in PA and there is a sentence G (the famous Gödel sentence) that is true just in case it is not provable in PA.

In provability logics, $\Box p$ is interpreted as a formula (of arithmetic) that expresses that what p denotes is provable in PA. Using this notation, sentences of provability logic express facts about provability. Suppose that $\bot$ is a constant of provability logic denoting a contradiction. Then $\sim\Box\bot$ says that PA is consistent and $\Box A \rightarrow A$ says that PA is sound in the sense that when it proves A, A is indeed true. Furthermore, the box may be iterated. So, for example, $\Box\sim\Box\bot$ makes the dubious claim that PA is able to prove its own consistency, and $\sim\Box\bot \rightarrow \sim\Box\sim\Box\bot$ asserts (correctly as Gödel proved) that if PA is consistent then PA is unable to prove its own consistency.

Although provability logics form a family of related systems, the system GL is by far the best known. It results from adding the following axiom to K:

(GL) $\Box(\Box A \rightarrow A) \rightarrow \Box A$

The axiom (4): $\Box A \rightarrow \Box\Box A$ is provable in GL, so GL is actually a strengthening of K4. However, axioms such as (M): $\Box A \rightarrow A$, and even the weaker (D): $\Box A \rightarrow \Diamond A$ are not available (nor desirable) in GL. In

provability logic, provability is not to be treated as a brand of necessity. PA may be defective (for all we can prove) so that if p is provable in PA (□p) it need not follow that ~p lacks a proof (~□~p = ◇p). PA might be inconsistent and so prove both p and ~p.

Axiom (GL) captures the content of Loeb's Theorem, an important result in the foundations of arithmetic. □A→A says that PA is sound for A, i.e. that if A were proven, A would be true. Such a claim might not be secure, since if PA goes awry, A might be provable and false. (GL) claims that if PA manages to prove the sentence that claims soundness for a given sentence A, then A is already provable in PA. Loeb's Theorem reports a kind of modesty on PA's part (Boolos, 1993, p. 55). PA never insists (proves) that a proof of A entails A's truth, unless it already has a proof of A to back up that claim.

It has been shown that GL is adequate for provability in the following sense. Let a sentence of GL be *always provable* exactly when the sentence of arithmetic it denotes is provable no matter how its variables are assigned values to sentences of PA. Then the provable sentences of GL are exactly the sentences that are always provable. This adequacy result has been extremely useful, since general questions concerning provability in PA can be transformed into easier questions about what can be demonstrated in GL.

GL can also be outfitted with a possible world semantics for which it is sound and complete. A corresponding condition on frames for GL-validity is that the frame be transitive, finite and irreflexive.

11. Quantifiers in Modal Logic

It would seem to be a simple matter to outfit a modal logic with the quantifiers ∀ (all) and ∃ (some). One would simply add the standard (or classical) rules for quantifiers to the principles of whichever propositional modal logic one chooses. However, systems of this kind create problems which have motivated some logicians to abandon classical quantifier rules in favor of the weaker rules of free logic (Garson, 1984). The controversy over whether classical principles should be adopted continues today.

The main points of disagreement can be traced back to decisions about how to handle the domain of quantification. The simplest alternative, the fixed-domain (sometimes called the possibilist) approach, assumes a single domain of quantification that contains all the possible objects. On the other hand, the world-relative (or actualist) interpretation, assumes that the domain of quantification changes from world to world, and contains only the objects that actually exist in a given world.

The fixed-domain approach requires no major adjustments to the classical machinery for the quantifiers. Modal logics that are adequate for fixed domain semantics can usually be axiomatized by adding principles of a propositional modal logic to classical quantifier rules together with the Barcan Formula (BF) (Barcan 1946). (For an account of some interesting exceptions see Cresswell (1995)).

(BF) ∀x□A→□∀xA.

The fixed-domain interpretation has advantages of simplicity and familiarity, but it does not provide a direct account of the semantics of certain quantifier expressions of natural language. We do not think that ‘Some man exists who signed the Declaration of Independence’ is true, at least not if we read ‘exists’ in the present tense. Nevertheless, this sentence was true in 1777, which shows that the domain for the natural language expression ‘some man exists who’ changes to reflect which men exist at different times. A related problem is that on the fixed-domain interpretation, the sentence $\forall y\Box\exists x(x=y)$ is valid. However, assuming that $\exists x(x=y)$ is read: y exists, $\forall y\Box\exists x(x=y)$ says that everything exists necessarily. However, it seems a fundamental feature of common ideas about modality that the existence of many things is contingent, and that different objects exist in different possible worlds.

The defender of the fixed-domain interpretation may respond to these objections by insisting that on his (her) reading of the quantifiers, the domain of quantification contains *all* possible objects, not just the objects that happen to exist at a given world. So the theorem $\forall y\Box\exists x(x=y)$ makes the innocuous claim that every *possible* object is necessarily found in the domain of all possible objects. Furthermore, those quantifier expressions of natural language whose domain is world (or time) dependent can be expressed using the fixed-domain quantifier $\exists x$ and a predicate letter E with the reading ‘actually exists’. For example, instead of translating ‘Some **M**an exists who **S**igned the Declaration of Independence’ by

$$\exists x(Mx\&Sx),$$

the defender of fixed domains may write:

$$\exists x(\mathbf{Ex\&}Mx\&Sx),$$

thus ensuring the translation is counted false at the present time. Cresswell (1991) makes the interesting observation that world-relative quantification has limited expressive power relative to fixed-domain quantification. World-relative quantification can be defined with fixed domain quantifiers and E, but there is no way to fully express fixed-domain quantifiers with world-relative ones. Although this argues in favor of the classical approach to quantified modal logic, the translation tactic also amounts to something of a concession in favor of free logic, for the world-relative quantifiers so defined obey exactly the free logic rules.

A problem with the translation strategy used by defenders of fixed domain quantification is that rendering the English into logic is less direct, since E must be added to all translations of all sentences whose quantifier expressions have domains that are context dependent. A more serious objection to fixed-domain quantification is that it strips the quantifier of a role which Quine recommended for it, namely to record robust ontological commitment. On this view, the domain of $\exists x$ must contain only entities that are ontologically respectable, and possible objects are too abstract to qualify. Actualists of this stripe will want to develop the logic of a quantifier $\exists x$ which reflects commitment to what is actual in a given world rather than to what is merely possible.

However, recent work on actualism tends to undermine this objection. For example, Linksy and Zalta

(1994) argue that the fixed-domain quantifier can be given an interpretation that is perfectly acceptable to actualists. Actualists who employ possible worlds semantics routinely quantify over possible worlds in their semantical theory of language. So it would seem that possible worlds are actual by these actualist's lights. By cleverly outfitting the domain with abstract entities no more objectionable than the ones actualists accept, Linsky and Zalta show that the Barcan Formula and classical principles can be vindicated. Note however, that actualists may respond that they need not be commited to the actuality of possible worlds so long as it is understood that quantifiers used in their theory of language lack strong ontological import. In any case, it is open to actualists (and non actualists as well) to investigate the logic of quantifiers with more robust domains, for example domains excluding possible worlds and other such abstract entities, and containing only the spatio-temporal particulars found in a given world. For quantifiers of this kind, a world-relative domains are appropriate.

Such considerations motivate interest in systems that acknowledge the context dependence of quantification by introducing world-relative domains. Here each possible world has its own domain of quantification (the set of objects that actually exist in that world), and the domains vary from one world to the next. When this decision is made, a difficulty arises for classical quantification theory. Notice that the sentence $\exists x(x=t)$ is a theorem of classical logic, and so $\Box\exists x(x=t)$ is a theorem of K by the Necessitation Rule. Let the term t stand for Saul Kripke. Then this theorem says that it is necessary that Saul Kripke exists, so that he is in the domain of every possible world. The whole motivation for the world-relative approach was to reflect the idea that objects in one world may fail to exist in another. If standard quantifier rulers are used, however, every term t must refer to something that exists in all the possible worlds. This seems incompatible with our ordinary practice of using terms to refer to things that only exist contingently.

One response to this difficulty is simply to eliminate terms. Kripke (1963) gives an example of a system that uses the world-relative interpretation and preserves the classical rules. However, the costs are severe. First, his language is artificially impoverished, and second, the rules for the propositional modal logic must be weakened.

Presuming that we would like a language that includes terms, and that classical rules are to be added to standard systems of propositional modal logic, a new problem arises. In such a system, it is possible to prove (CBF), the converse of the Barcan Formula.

(CBF) $\Box\forall xA\rightarrow\forall x\Box A.$

This fact has serious consequences for the system's semantics. It is not difficult to show that every world-relative model of (CBF) must meet condition (ND) (for ‘nested domains’).

(ND) If wRv then the domain of w is a subset of the domain of v.

However (ND) conflicts with the point of introducing world-relative domains. The whole idea was that existence of objects is contingent so that there are accessible possible worlds where one of the things in

our world fails to exist.

A straightforward solution to these problems is to abandon classical rules for the quantifiers and to adopt rules for free logic (FL) instead. The rules of FL are the same as the classical rules, except that inferences from $\forall$xRx (everything is real) to Rp (Pegasus is real) are blocked. This is done by introducing a predicate ‘E’ (for ‘actually exists’) and modifying the rule of universal instantiation. From $\forall$xRx one is allowed to obtain Rp only if one also has obtained Ep. Assuming that the universal quantifier $\forall$x is primitive, and the existential quantifier $\exists$x is defined by $\exists$xA =df ~$\forall$x~A, then FL may be constructed by adding the following two principles to the rules of propositional logic

> Universal Generalization. If $B \rightarrow A(y)$ is a theorem, so is $B \rightarrow \forall xA(x)$.

> Universal Instantiation. $(\forall xA(x)\ \&\ En) \rightarrow A(n)$

(Here it is assumed that A(x) is any well-formed formula of predicate logic, and that A(y) and A(n) result from replacing y and n properly for each occurrence of x in A(x).) Note that the principle of universal generalization is standard, but that the instantiation axiom is restricted by mention of En in the antecedent. In FL, proofs of formulas like $\exists x\Box(x=t)$, $\forall y\Box\ \exists x(x=y)$, (CBF), and (BF) which seem incompatible with the world-relative interpretation, are blocked.

One philosophical objection to FL is that E appears to be an existence predicate, and many would argue that existence is not a legitimate property like being green or weighing more than four pounds. So philosophers who reject the idea that existence is a predicate may object to FL. However in most (but not all) quantified modal logics that include identity (=) these worries may be skirted by defining E as follows.

> $Et\ =_{df}\ \exists x(x=t)$.

The most general way to formulate quantified modal logic is to create FS by adding the rules of FL to a given propositional modal logic S. In situations where classical quantification is desired, one may simply add Et as an axiom to FS, so that the classical principles become derivable rules. Adequacy results for such systems can be obtained for most choices of the modal logic S, but there are exceptions.

A final complication in the semantics for quantified modal logic is worth mentioning. It arises when non-rigid expressions such as ‘the inventor of bifocals’, are introduced to the language. A term is non-rigid when it picks out different objects in different possible worlds. The semantical value of such a term can be given by what Carnap (1947) called an individual concept, a function that picks out the denotation of the term for each possible world. One approach to dealing with non-rigid terms is to employ Russell's theory of descriptions. However, in a language that treats non rigid expressions as genuine terms, it turns out that neither the classical nor the free logic rules for the quantifiers are acceptable. (The problem can not be resolved by weakening the rule of substitution for identity.) A solution to this problem is to employ a more general treatment of the quantifiers, where the domain of quantification contains

individual concepts rather than objects. This more general interpretation provides a better match between the treatment of terms and the treatment of quantifiers and results in systems that are adequate for classical or free logic rules (depending on whether the fixed domains or world-relative domains are chosen).

Temporal Logic

The term Temporal Logic has been broadly used to cover all approaches to the representation of temporal information within a logical framework, and also more narrowly to refer specifically to the modal-logic type of approach introduced around 1960 by Arthur Prior under the name of Tense Logic and subsequently developed further by logicians and computer scientists.

Applications of Temporal Logic include its use as a formalism for clarifying philosophical issues about time, as a framework within which to define the semantics of temporal expressions in natural language, as a language for encoding temporal knowledge in artificial intelligence, and as a tool for handling the temporal aspects of the execution of computer programs.

Modal-logic approaches to temporal logic

Tense Logic

Tense Logic was introduced by Arthur Prior (1957, 1967, 1969) as a result of an interest in the relationship between tense and modality attributed to the Megarian philosopher Diodorus Cronus (ca. 340-280 B.C.). For the the historical context leading up to the introduction of Tense Logic, as well as its subsequent developments, see Øhrstrøm and Hasle, 1995.

The logical language of Tense Logic contains, in addition to the usual truth-functional operators, four modal operators with intended meanings as follows:

P	"It has at some time been the case that ..."
F	"It will at some time be the case that ..."
H	"It has always been the case that ..."
G	"It will always be the case that ..."

P and F are known as the *weak tense operators*, while H and G are known as the *strong tense operators*. The two pairs are generally regarded as interdefinable by way of the equivalences

$$Pp \equiv \neg H \neg p$$
$$Fp \equiv \neg G \neg p$$

On the basis of these intended meanings, Prior used the operators to build formulae expressing various philosophical theses about time, which might be taken as axioms of a formal system if so desired. Some examples of such formulae, with Prior's own glosses (from Prior 1967), are:

$Gp \rightarrow Fp$	"What will always be, will be"
$G(p \rightarrow q) \rightarrow (Gp \rightarrow Gq)$	"If p will always imply q, then if p will always be the case, so will q"
$Fp \rightarrow FFp$	"If it will be the case that p, it will be --- in between --- that it will be"
$\neg Fp \rightarrow F \neg Fp$	"If it will never be that p then it will be that it will never be that p"

Prior (1967) reports on the extensive early work on various systems of Tense Logic obtained by postulating different combination of axioms, and in particular he considered in some detail what light a logical treatment of time can throw on classic problems concerning time, necessity and existence; for example, "deterministic" arguments that have been advanced over the ages to the effect that "what will be, will necessarily be", corresponding to the modal tense-logical formula $Fp \rightarrow \Box Fp$.

Of particular significance is the system of *Minimal Tense Logic* K_t, which is generated by the four axioms

$p \rightarrow HFp$	"What is, has always been going to be"
$p \rightarrow GPp$	"What is, will always have been"
$H(p \rightarrow q) \rightarrow (Hp \rightarrow Hq)$	"Whatever always follows from what always has been, always has been"

$G(p \rightarrow q) \rightarrow (Gp \rightarrow Gq)$	"Whatever always follows from what always will be, always will be"

together with the two rules of temporal inference:

RH: From a proof of p, derive a proof of Hp
RG: From a proof of p, derive a proof of Gp

and, of course, all the rules of ordinary Propositional Logic. The theorems of K_t express, essentially, those properties of the tense operators which do not depend on any specific assumptions about the temporal order. This characterisation is made more precise below.

Tense Logic is obtained by adding the tense operators to an existing logic; above this was tacitly assumed to be the classical Propositional Calculus. Other tense-logical systems are obtained by taking different logical bases. Of obvious interest is tensed predicate logic, where the tense operators are added to classical First-order Predicate Calculus. This enables us to express important distinctions concerning the logic of time and existence. For example, the statement *A philosopher will be a king* can be interpreted in several different ways, such as

∃x(Philosopher(x) & F King(x))	Someone who is now a philosopher will be a king at some future time
∃xF(Philosopher(x) & King(x))	There now exists someone who will at some future time be both a philosopher and a king
F∃x(Philosopher(x) & F King(x))	There will exist someone who is a philosopher and later will be a king
F∃x(Philosopher(x) & King(x))	There will exist someone who is at the same time both a philosopher and a king

The interpretation of such formulae is not unproblematic, however. The problem concerns the domain of quantification. For the second two formulae above to bear the interpretations given to them, it is necessary that the domain of quantification is always relative to a time: thus in the semantics it will be necessary to introduce a domain of quantification D(t) for each time t. But this can lead to problems if we want to establish relations between objects existing at different times, as for example in the statement "One of my friends is descended from a follower of William the Conqueror".

These problems are related to the so-called *Barcan formulae* of modal logic, a temporal analogue of which is

$F\exists x p(x) \rightarrow \exists x F p(x)$ ("If there will be something that is p, then there is now something that will be p")

For this formula to be true, we require the "domain cumulation" principle, which says that the whole domain of quantification D(t) at time t is included in all the domains D(t′) for times t′ later than t. For more on this and related matters, see van Benthem, 1995, Section 7.

Extensions to Tense Logic

Soon after its introduction, the basic "PFGH" syntax of Tense Logic was extended in various ways, and such extensions have continued to this day. Some important examples are the following:

The binary temporal operators S and U ("since" and "until"). These were introduced by Kamp (1968). The intended meanings are

Spq	"q has been true since a time when p was true"
Upq	"q will be true until a time when p is true"

It is possible to define the one-place tense operators in terms of S and U as follows:

$$Pp \equiv Sp(p \vee \neg p)$$
$$Fp \equiv Up(p \vee \neg p)$$

The importance of the S and U operators is that they are expressively complete with respect to first-order temporal properties on continuous, strictly linear temporal orders (which is not true for the one-place operators on their own).

Metric tense logic. Prior introduced the notation Fnp to mean "It will be the case the interval n hence that p". We do not need a separate notation Pnp since we can write F(-n)p for "It was the case the interval n ago that P". The case n=0 gives us the present tense. We can define the general, non-metric operators by

$$Pp \equiv \exists n(n<0 \; \& \; Fnp)$$
$$Fp \equiv \exists n(n>0 \; \& \; Fnp)$$
$$Hp \equiv \forall n(n<0 \rightarrow Fnp)$$
$$Gp \equiv \forall n(n>0 \rightarrow Fnp)$$

The "next time" operator O. This operator assumes that the time series consists of a discrete sequence of atomic times. The formula Op is then intended to mean that p is true at the immediately succeeding time step. Given that time is discrete, it can be defined in terms of the "until" operator U by

$$Op \equiv Up(p \& \neg p)$$

which says that p will be true at some future time, between which and the present time nothing is true. This can only mean the time immediately following the present in a discrete temporal order.

In discrete time, the future-tense operator F is related to the next-time operator by the equivalence

$$Fp \equiv Op \vee OFp.$$

Indeed, F can here be *defined* as the least fixed point of the transformation which maps an arbitrary propositional operator X onto the operator $\lambda p.Op \vee OXp$.

One could similarly define a past-time version of O; but since the main usefulness of this particular operator has been in relation to the logic of computer programming, where one is mainly interested in execution sequences of programs extending into the future, this has not so often been done.

Semantics of Tense Logic

The standard model-theoretic semantics of Tense Logic is closely modelled on that of Modal Logic. A *temporal frame* consists of a set T of entities called times together with an ordering relation < on T. This defines the "flow of time" over which the meanings of the tense operators are to be defined. An interpretation of the tense-logical language assigns a truth value to each atomic formula at each time in the temporal frame. Given such an interpretation, the meanings of the weak tense operators can be defined using the rules

> Pp is true at t if and only if p is true at some time t' such that $t'<t$
> Fp is true at t if and only if p is true at some time t' such that $t<t'$

from which it follows that the meanings of the strong operators are given by

> Hp is true at t if and only if p is true at all times t' such that $t'<t$
> Gp is true at t if and only if p is true at all times t' such that $t<t'$

We can now provide a precise characterisation of system K_t of Minimal Tense Logic. The theorems of K_t are precisely those formulae which are true at all times under all interpretations over all temporal frames.

Many tense-logical axioms have been suggested as expressing this or that property of the flow of time, and the semantics gives us a precise way of defining this correspondence between tense-logical formulae and properties of temporal frames. A formula p is said to *characterise* a set of frames F if

- p is true at all times under all interpretations over any frame in F.
- For any frame not in F, there is an interpretation which makes p false at some time.

Thus any theorem of K_t characterises the class of all frames.

A first-order formula in < determines a class of frames, namely those in which the formula is true. A tense-logical formula p corresponds to a first-order formula q just so long as p characterises the class of frames for which q is true. Some well-known examples of such pairs of formulae are:

$Hp \rightarrow Pp$	$\forall t \exists t'(t' < t)$	(unbounded in the past)
$Gp \rightarrow Fp$	$\forall t \exists t'(t < t')$	(unbounded in the future)
$Fp \rightarrow FFp$	$\forall t,t'(t < t' \rightarrow \exists t''(t < t'' < t'))$	(dense ordering)
$FFp \rightarrow Fp$	$\forall t,t'(\exists t''(t < t'' < t') \rightarrow t < t')$	(transitive ordering)
$FPp \rightarrow Pp \vee p \vee Fp$	$\forall t,t',t''((t < t'' \ \& \ t' < t'') \rightarrow (t < t' \vee t = t' \vee t' < t))$	(linear in the past)
$PFp \rightarrow Pp \vee p \vee Fp$	$\forall t,t',t''((t'' < t \ \& \ t'' < t') \rightarrow (t < t' \vee t = t' \vee t' < t))$	(linear in the future)

However, there are tense-logical formulae (such as $GFp \rightarrow FGp$) which do not correspond to any first-order temporal frame properties, and there are first-order temporal frame properties (such as *irreflexivity*, expressed by $\forall t \neg(t < t)$) which do not correspond to any tense-logical formula. For details, see van Benthem (1983).

Predicate-logic approaches to temporal logic

The method of temporal arguments

In this method, the temporal dimension is captured by augmenting each time-variable proposition or predicate with an extra argument-place, to be filled by an expression designating a time, as for example

Kill(Brutus,Caesar,44BC).

If we introduce into the first-order language a binary infix predicate < denoting the temporal ordering relation "earlier than", and a constant "now" denoting the present moment, then the tense operators can be readily simulated by means of the following correspondences, which not surprisingly bear more than a passing resemblance to the formal semantics for Tense Logic given above. Where p(t) represents the result of introducing an extra temporal argument place to the time-variable predicates occurring in p, we have:

Pp	$\exists t(t<now \,\&\, p(t))$
Fp	$\exists t(now<t \,\&\, p(t))$
Gp	$\forall t(t<now \rightarrow p(t))$
Hp	$\forall t(now<t \rightarrow p(t))$

Before the advent of Tense Logic, the method of temporal arguments was the natural choice of formalism for the logical expression of temporal information.

State and event-type reification

The method of temporal arguments encounters difficulties if it is desired to model *aspectual* distinctions between, for example, states, events and processes. Propositions reporting states (such as "Mary is asleep") have *homogeneous* temporal incidence, in that they must hold over any subintervals of an interval over which they hold (e.g., if Mary is asleep from 1 o'clock to 6 o'clock then she is asleep from 1 o'clock to 2 o'clock, from 2 o'clock to 3 o'clock, and so on). By contrast, propositions reporting events (such as "John walks to the station") have inhomogeneous temporal incidence; more precisely, such a proposition is not true of *any* proper subinterval of an interval of which it is true (e.g., if John walks to the station over the interval from 1 o'clock to a quarter past one, then it is not the case that he walks to the station over the interval from 1 o'clock to five past one --- rather, over that interval he walks part of the way to the station).

The method of state and event-type reification was introduced to cater for distinctions of this kind. It is an approach that has been especially popular in Artificial Intelligence, where it is particularly associated with the name of James Allen, whose influential paper (Allen 1984) is often cited in this connection. In this approach, state and event types are denoted by terms in a first-order theory; their temporal incidence is expressed using relational predicates "Holds" and "Occurs", as for example,

Holds(Asleep(Mary),(1pm,6pm))
Occurs(Walk-to(John,Station),(1pm,1.15pm))

where terms of the form (t,t') denote time intervals in the obvious way.

The homogeneity of states and inhomogeneity of events is secured by axioms such as

$$\forall s,i,i'(\mathrm{Holds}(s,i) \,\&\, \mathrm{In}(i',i) \rightarrow \mathrm{Holds}(s,i'))$$
$$\forall e,i,i'(\mathrm{Occurs}(e,i) \,\&\, \mathrm{In}(i',i) \rightarrow \neg\mathrm{Occurs}(e,i'))$$

where "In" expresses the proper subinterval relation.

Event-token reification

The method of event-token reification was proposed by Donald Davidson (1967) as a solution to the so-called "variable polyadicity" problem. The problem is to give a formal account of the validity of such inferences as

> John saw Mary in London on Tuesday.
> Therefore, John saw Mary on Tuesday.

The key idea is that each event-forming predicate is endowed with an extra argument-place to be filled with a variable ranging over event-tokens, that is, particular dated occurrences. The inference above is then cast in logical form as

> ∃e(See(John,Mary,e) & Place(e,London) & Time(e,Tuesday)),
> Therefore, ∃e(See(John,Mary,e) & Time(e,Tuesday)).

In this form, the inference does not require any additional logical apparatus over and above standard first-order predicate logic; on that basis, the validity of the inference is considered to be explained. This approach has also been used in a computational context in the Event Calculus of Kowalski and Sergot (1986).

Philosophical issues

Prior's motivation for inventing Tense Logic was largely philosophical, his idea being that the precision and clarity afforded by a formal logical notation was indispensible for the careful formulation and resolution of philosophical issues concerning time. See the article on Arthur Prior for a discussion of some of these.

The rivalry between the modal and first-order approaches to formalising the logic of time reflects an important set of underlying philosophical issues related to the work of McTaggart. This work is especially well-known, in the context of temporal logic, for introducing the distinction between the "A-series" and the "B-series". By the "A-series" is meant, essentially, the characterisation of events as Past, Present, or Future. By contrast, the "B-series" involves their characterisation as relatively "Earlier" or "Later". A-series representations of time inescapably single out some particular moment as present; of course, at different times, different moments are present --- a circumstance which, followed to what appeared to be its logical conclusion, led McTaggart to assert that time itself was unreal (see Mellor, 1981). B-series representations have no place for a concept of the present, instead taking the form of a synoptic view of all time and the (timeless) interrelations between its parts.

There is a clear affinity between the A-series and the modal approach and between the B-series and the first-order approach. In the terminology of Massey (1969), adherents of the former approach are called "tensers" while adherents of the latter are called "detensers". This issue is related in turn to the question of how seriously to take the representation of space-time as a single four-dimensional entity in which the four dimensions are at least in some respects on a similar footing. In view of the Theory of Relativity, it can be argued that this issue is not so much a matter for Philosophy as for Physics.

Applications of Temporal Logic

Applications to natural language

Prior (1967) lists amongst the precursors of Tense Logic Hans Reichenbach's (1947) analysis of the tenses of English, according to which the function of each tense is to specify the temporal relationships amongst a set of three times related to the utterance, namely S, the speech time, R, the reference time, and E, the event time. In this way Reichenbach was neatly able to distinguish between the simple past "I saw John", for which R=E<S, and the present perfect "I have seen John", for which E<R=S, the former statement referring to a past time coincident with the event of my seeing John, the latter referring to the present time, relative to which my seeing John is past.

Prior notes that Reichenbach's analysis is inadequate to account for the full range of tense usage in natural language. Subsequently much work has been done to refine the analysis, not only of tenses but also other temporal expressions in language such as the temporal prepositions and connectives ("before", "after", "since", "during", "until"), using the many varieties of temporal logic. For some examples, see Dowty (1979), Galton (1984), Taylor (1985), Richards *et al.* (1989).

Applications in artificial intelligence

We have already mentioned the work of Allen (1984), which is concerned with finding a general framework adequate for all the temporal representations required by AI programs. The Event Calculus of Kowalski and Sergot (1986) is pursued more specifically within the framework of logic programming, but is otherwise similarly general in character. A useful survey of issues involving time and temporal reasoning in AI is Galton (1995).

Much of the work on temporal reasoning in AI has been closely tied up with the notorious *frame problem*, which arises from the necessity for any automated reasoner to know, or be able to deduce, not only those properties of the world which *do* change as the result of any event or action, but also those properties which do *not* change. In everyday life, we normally handle such facts fluently without consciously adverting to them: we take for granted without thinking about it, for example, that the colour of a car does not normally change when one changes gear. The frame problem is concerned with how to formalise the logic of actions and events in such a way that indefinitely many inferences of this kind are

made available without our having to encode them all explicitly. A seminal work in this area is McCarthy and Hayes (1969). A useful recent reference for the frame problem is Shanahan, 1997.

Applications in computer science

Following Pnueli (1977), the modal style of Temporal Logic has found extensive application in the area of Computer Science concerned with the specification and verification of programs, especially concurrent programs in which the computation is performed by two or more processors working in parallel. In order to ensure correct behaviour of such a program it is necessary to specify the way in which the actions of the various processors are interrelated. The relative timing of the actions must be carefully co-ordinated so as to ensure that integrity of the information shared amongst the processors is maintained. Amongst the key notions here is the distinction between "liveness" properties of the tense-logical form Fp, which ensure that desirable states will obtain in the course of the computation, and "safety" properties of the form Gp, which ensure that undesirable states will never obtain.

Further information may be found in Galton (1987), Goldblatt (1987), Bolc and Szalas (1995).

Arthur Prior

Arthur Prior (1914-1969) undertook pioneering work in intensional logic at a time when modality and intensional concepts in general were under attack. He invented tense logic and was principal theoretician of the movement to apply modal syntax to the formalisation of a wide variety of phenomena. Prior and Carew Meredith devised a version of the possible worlds semantics several years before Kripke published his first paper on the topic. An iconoclast and a resourceful innovator, Prior inspired many to undertake work in intensional logic.

Work on Tense Logic

Prior's most significant achievement was undoubtedly the invention and development of tense logic. His earliest mention of a logic of time-distinctions is to be found in the penultimate chapter of his unpublished manuscript *The Craft of Formal Logic* (completed in 1951). Following von Wright in ‘Deontic Logic’ he remarks that there are other groups of modal predicates to be set alongside the ordinary or ‘alethic’ modes of necessity and possibility. Prior refers to these non-alethic modalities as ‘quasi-modals’. After noting that Peter of Spain classified adverbial distinctions of time as modes he says (p. 750):

> That there should be a modal logic of time-distinctions has been suggested in our own day by Professor Findlay.

Findlay's paper ‘Time: A Treatment of Some Puzzles’ had appeared in the *Australasian Journal of Psychology and Philosophy* in 1941. Prior became aware of it as a result of its appearance in Flew's 1951 collection *Essays on Logic and Language*, which arrived in New Zealand just as Prior was writing the

final chapters of *The Craft.* The suggestion Prior refers to is barely more than a passing comment: "[O]ur conventions with regard to tenses are so well worked out that we have practically the materials in them for a formal calculus", wrote Findlay. He continued in a footnote:

> The calculus of tenses should have been included in the modern development of modal logics. It includes such obvious propositions as that
>
> x present ↔ (x present) present;
>
> x future ↔ (x future) present ↔ (x present) future;
>
> also such comparatively recondite propositions as that
>
> (x).(x past) future; i.e., all events, past, present and future, *will* be past.

Prior's first paper on the logic of tenses, ‘Three-Valued Logic and Future Contingents’, appeared in the *Philosophical Quarterly* for 1953. In 1949 he had learned from Geach's review of Julius Weinberg's *Nicolaus of Autricourt: A Study in 14th Century Thought* that for the scholastics an expression like ‘Socrates is sitting down’ is complete, in the sense of being assertable as it is, and is true at certain times, false at others. Prior had been brought up on the view -- prevalent even today -- that such an expression is incomplete until a time-reference is supplied, and hence that one cannot speak of the truth-value of the expression as altering with the passage of time. This was a crucial discovery for Prior: the idea that propositions which are subject to tense-inflections are liable to be true at one time and false at another was to become central to his philosophy. In a summary of his mature views on temporal realism composed nearly two decades later he wrote:

> Certainly there are unchanging truths, but there are changing truths also, and it is a pity if logic ignores these, and leaves it ... to comparatively informal ‘dialecticians’ to study the more ‘dynamic’ aspects of reality. (Prior 1996a: 46.)

Geach's review sent Prior to the sources, and he found that the ‘Socrates is sitting down’ example is not only in the scholastics but in Aristotle. Moreover, he discovered that Aristotle speaks of some propositions about the future - namely those about such events as are not already predetermined - as being neither true nor false when they are uttered, on the ground that there is as yet no definite fact with which they can accord or conflict. Prior quotes Aristotle's argument for believing that there are such events (De Interpretatione, ch.9): if there were not "there would be no need to deliberate or take trouble, on the supposition that if we should adopt a certain course, a certain result would follow, while, if we did not, the result would not follow" (1953: 232-3). This appealed to Prior, once a Barthian Calvinist but now on the side of indeterminism and freewill. There can be no doubt that Prior's interest in tense logic was bound up with his belief in the existence of real freedom (see, for example, Prior 1996b).

Over thirty years earlier, inspired by these same passages of Aristotle, Lukasiewicz had devised a three-

valued calculus whose third value, $\frac{1}{2}$, attached to propositions referring to future contingencies (Lukasiewicz 1920). Prior's 1953 article ‘Three-Valued Logic and Future Contingents’ is an exposition and defence of Lukasiewicz's system (which he had read about in Lewis and Langford's *Symbolic Logic* and in Jordan's monograph *The Development of Mathematical Logic and of Logical Positivism in Poland Between the Two Wars*). Prior thought, at this stage, that the logic of tensed propositions could be three-valued and that of tenseless propositions two-valued (1967: 16).

> In sum, three-valued logic does seem to bring new precision to our handling of statements with tenses (as opposed to the fundamentally tenseless propositions of the common systems); and we may say that Lukasiewicz has, by means of it, done for Aristotle's chapter on ‘future contingents’ what he has done elsewhere for the Aristotelian theory of the syllogism. (Prior 1953: 325.)

However, the Lukasiewicz system is far from being the ‘calculus of tenses’ at which Findlay had hinted. The system contains explicit syntactic representations of the alethic modalities but there is no syntactic representation of tense. Moreover, the simple addition of another truth value is hardly the means by which to do justice to Prior's key insight that propositions subject to tense-inflection can *change* in truth value with the passage of time: ‘Socrates is sitting down’ can be true at one time, false at another, and adding a third value does not help represent this change. It was some months before Prior realised that the use of off-the-shelf modal syntax was all that was required for the representation of this dynamical feature of tensed propositions. It was simply a matter of taking seriously the idea that he had discussed in *The Craft*: tense is a species of modality.

In 1953 Prior read of the work of the Megarian logician Diodorus Chronos in Benson Mates' book *Stoic Logic*. Prior later wrote of Diodorus that he "seems to have been an ancient Greek W.V. Quine, who regarded the Aristotelian logic of possibility and necessity with some scepticism, but offered nevertheless some ‘harmless’ senses that might be attached to modal words" (1967: 16). Diodorus defined the possible as what is or will be true: according to Diodorus, what actually happens is all that *can* happen. Prior found this deterministic definition uncongenial and set himself the task of locating a fallacy in the argument that Diodorus used to support it, the so-called Master Argument:

> The aim of the Master Argument, as I conceive it, was to refute the Aristotelian view that while it is now beyond the power of men or gods to affect the past, there are alternative futures between which choice is possible. Against this, Diodorus held that the possible is simply what either is or will be true. (1962a: 138; see also 1967: 33.)

Consideration of the Master Argument brought together three of Prior's great interests: indeterminism, modal logic, and the logic of time. In the course of his reflections on the argument, Findlay's footnote pushed its way to the front of his mind. His wife Mary remembers "his waking me one night, coming and sitting on my bed, and reading a footnote from John Findlay's article on time, and saying he thought one could make a formalised tense logic." His first explorations of this calculus of tenses appeared in his article ‘Diodoran Modalities’, completed by early 1954 and published in 1955. (‘Diodoran’ is Prior's

term, ‘Diodorean’ is Mates's. In 1958 Prior switched to the latter.) In it he wrote:

> I here propose to do something a little different, namely to employ the ordinary propositional variables ‘p’, ‘q’, ‘r’ etc., for ‘propositions’ in the Diodoran sense [i.e. propositions which ‘may be true at one time and false at another’] and to use certain operators which take such propositions as arguments, and which form functions taking such propositions as values. I shall use ‘Fp’ for ‘It will be the case that p’. (1955b: 205.)

The axioms and rules of the calculus that Prior sets out in this article owe much to von Wright's 1951 axiomatisation of Lewis' modal system S4 (*An Essay in Modal Logic*, Appendix II). Von Wright obtains S4 by adding the following axioms and rules to the classical propositional calculus (Lp is defined as -M-P):

> W1. p → Mp
>
> W2. M(pvq) ↔ (Mp)v(Mq)
>
> W3. MMp → Mp
>
> RE. If X ↔ Y is a thesis, so is MX ↔ MY
>
> RL. If X is a thesis so is LX.

Substituting his new operator F for M throughout the axioms produced, in the case of W1, a clear falsehood and in the case of W2 and W3, formulae which he found ‘obvious enough’. The result of substituting F into RE also made good sense to him. To deal with RL he introduced a tense-prefix G by means of a definition paralleling von Wright's definition of L, viz. Gp=-F-p; he read G as ‘it will be always be the case that’. Thus his 1953/54 calculus of tenses was the system produced by adding the F-analogues of W2, W3 and RE, and the G-analogue of RL, to the classical propositional calculus. (Prior remarks that an operator P may be introduced for ‘It has been the case that p’ but states no axioms or rules concerning it.) He shows that if, following Diodorus, Mp is defined as pvFp, von Wright's three modal axioms and two rules are all derivable in his calculus.

In a matchless piece of philosophical reconstruction Prior expresses the conclusion of the Master Argument, that what neither is nor will be true is not possible, as (-p&-Fp) → -Mp and derives it in his calculus from Diodorus' premisses, Pp → -M-Pp and -Mq → (L(p → q) → -Mp), together with two ‘broad assumptions about time, likely to have been taken for granted both by Diodorus and by his main opponents’: p → HFp and (-p&-Fp) → P-Fp. So the Master Argument is indeed valid. The fallacy, Prior tells us, lies with the second ‘broad assumption’, (-p&-Fp) → P-Fp (which says: when anything neither is nor will be the case, it has been the case that it will not be the case). This, Prior tells us, is not true if p refers to a future contingency (and thus has the truth value $\frac{1}{2}$ or ‘indeterminate’). Where p is indeterminate both Fp and -Fp are indeterminate, so the consequent of the disputed formula, P-Fp, is

false. -p must also be indeterminate (for if the negation of p were determinate p could not be indeterminate). Thus the antecedent of the disputed formula, -p&-Fp, is indeterminate, since both its conjuncts are indeterminate. According to the Lukasiewicz truth-table, an indicative conditional with a false consequent and an indeterminate antecedent is not true but indeterminate.

$\rightarrow$	1	$\frac{1}{2}$	0
1	1	$\frac{1}{2}$	0
$\frac{1}{2}$	1	1	$\frac{1}{2}$
0	1	1	1

Thus Prior is able to "deny that propositions of the form [(-p & -Fp) $\rightarrow$ P-Fp] are in all cases true".

This reasoning of Prior's is persuasive only if one accepts the Lukasiewicz truth-table. Yet are there not indicative conditionals with false consequents and indeterminate antecedents that are *true*? For example, let Fp be ‘I will kill myself’, and let us suppose that Fp is indeterminate (since I have not yet decided). So PFp is false: there has as yet been no time at which Fp is true. Yet it seems excessively harsh always to withhold the value True from the indicative conditional ‘If Fp then PFp’ (harsh given, at any rate, that temporal succession is transitive and that atypical moments such as the first moment of time are not under consideration). The difficulty is that in the conditional form a statement that is actually indeterminate in value, Fp, is supposed *true*. If Fp is now true then the present moment lies in an epoch throughout which it is the case that p's future truth is determined. Unless the moment of utterance happens to be the very first moment of this epoch there are past moments at which Fp is true, so PFp is now true. So, given some suitable assumption concerning such epochs, which for the present purposes may be chosen ad libitum (for example, it will suffice to assume that such epochs are always open intervals in continuous linear time), it is the case that if Fp is true then PFp is true. The claim that the conditional ‘if Fp then PFp’ is indeterminate simply because its antecedent happens to be so (and its consequent false) cannot be sustained in the present situation, for what the above reasoning shows is that (under the assumption) the combination antecedent True, consequent False cannot arise.

At bottom what this indicates, of course, is that the two-valued equivalence between -pvq and p $\rightarrow$ q does not extend to the three-valued case. -pÃq may be indeterminate and yet, as in the present example, there be no principled reason for withholding the value True from p $\rightarrow$ q. Lukasiewicz's idea that propositions about the future may be assigned a third truth-value is not as straightforward as it may seem. Prior himself later came to see that "[t]he truth-functional technique seems simply out of place" where indeterminate propositions are concerned (1967: 135). It was the treatment of conjunction that particularly troubled Prior. According to the Lukasiewicz truth-table, p&q is indeterminate where p and q are both indeterminate, yet as Prior remarks, if q is the negation of an indeterminate p then p&q is not indeterminate even though both its constituents are. The proposition ‘There both will and won't be a sea battle tomorrow’ is, Prior says, "plain false".

The Master Argument for determinism continued to exercise Prior for the rest of his life, and some of the

most useful and mathematically most interesting parts of his work were inspired by his thoughts on it. To choose just one example, from computer science, the calculi that Prior developed in response to the idea that the Master Argument is defeated if time is conceived as branching into the future have become useful for describing and verifying the behaviour of concurrent and distributed processing systems.

The tense calculus that Prior worked out in ‘Diodoran Modalities’ was hardly complete. For one thing there were no axioms or rules for the past tense operator P, and for another the calculus' two axioms, FFp → Fp and F(pvq) ↔ (Fp)v(Fq), had been chosen in an almost haphazard manner, by transforming certain axioms of a calculus designed for a rather different purpose. Prior duly set about expanding his calculus. He worked fast, and in August 1954 he presented a system of far greater sophistication in his Presidential Address to the second New Zealand Congress of Philosophy, held in Wellington. (Prior himself had organised the first Congress in Christchurch the previous year.)

His first step was to add two additional axioms concerning futurity, Gp → Fp and Fp → FFp. The former is the tense-analogue of Lp → Mp, a thesis whose derivation involves von Wright's axiom W1 (which is false under a tense-logical interpretation). The second of the new axioms is the converse of one of the original axioms. Prior remarks that it is suggested by ‘common notions on the subject of time’. Next he made a simplification which drew on a recent proof by Sobocinski that von Wright's weakest system M is equivalent to Feys' system T: by taking G as undefined and defining F as -G-, he was able to replace the somewhat unwieldy axiom F(pvq) ↔ (Fp)v(Fq) by G(p → q) → (Gp → Gq) (Sobocinski 1953).

This calculus of ‘pure futurity’ can be transformed into a calculus of ‘pure pastness’ by replacing F by P and G by H (‘It has always been the case that’) throughout the axioms, rules and definition. (Charles Hamblin was later to describe this process and its reverse as producing the ‘mirror-image’ of what one starts with.) Like the alethic systems, both these ‘pure’ calculi are *monomodal*. That is, each contains only one undefined modal operator. Prior wanted a ‘full tense calculus in F and P’: a *bimodal* logic (i.e. a logic containing two undefined modal operators). To obtain the bimodal system it was not enough to simply bundle together the futurity axioms and rules with their mirror images, for the two tense operators would then remain independent of one another. Some *interactive* axioms, "laws which relate to the interaction of pastness and futurity", were also required. Prior chose p → GPp and p → HFp. He found the first of these in William of Ockham's *Tractatus de Praedestinatione* and the second was one of the formulae he himself had used in his reconstruction of the Master-Argument. Thus Prior constructed the first multimodal system.

Prior honoured Findlay by proving one of the propositions stated in his footnote as the first theorem of the full tense calculus: all events, past, present and future, will be past. In tense-logical notation this is (pvPpvFp) → FPp, a formula that Prior was later to refer to simply as Findlay's law. (Prior describes Findlay's own suggested symbolisation of the proposition, (x).(x past) future, as ‘unfortunate’, since "the formula suggests that *everything* will have been the case (even permanent falsehoods)" (1967: 9).)

In ‘Diodoran Modalities’ Prior was content to describe FFp → Fp as ‘obvious enough’. By the time of the Wellington Congress his thinking had moved forward considerably. In a strikingly original section of

a strikingly original paper he set out what he called the l-calculus (he was later to prefer the term ‘U-calculus’). In the l-calculus the propositions of the tense calculus are treated as predicates expressing properties of dates, the latter being represented by name-variables x, y, z. The concatenation ‘px’ is read as ‘p at x’. ‘l’ is a binary relation taking dates as arguments and is read ‘is later than’. Using an arbitrary date z to represent the time of utterance, Fp is equated with (∃x)(lxz & px) (‘p at some time later than z’), and Pp with (∃x)(lzx & px) (‘p at some time earlier than z’). Gp and Hp are equated with the universal quantifications (x)(lxz → px) and (x)(lzx → px), respectively. Prior's key idea was that by imposing various conditions on the relation l, analogues of the axioms of the tense calculus can be derived in the l-calculus. (It was this idea that he and Carew Meredith were to exploit two years later in devising the possible worlds semantics for modal logic.)

Prior discovered that FFp → Fp and its mirror-image require for their derivation the condition lxy → (lyz → lxz), asserting that the later-than relation is transitive. Fp → FFp and its mirror-image require the condition lxz → (Ey)(lxy&lyz), which asserts that ‘between any two dates there is another date’. Gp → Fp requires the condition that ‘there is a date later than any given date’, (Ex)lxz (mutatis mutandis for the mirror-image). Prior notes that no conditions are required for the derivation in the l-calculus of the two interactive axioms p → GPp and p → HFp nor for the axioms G(p → q) → (Gp → Gq) and H(p → q) → (Hp → Hq): in the case of these formulae the standard machinery of truth-functional and quantificational logic suffices for their derivation (this applies also to the two rules of the calculus). It was these latter formulae that Lemmon later took as axioms for his minimal tense logic K_t, a system making no assumptions concerning contingent properties of the later-than relation.

Prior closes this section with a warning against regarding this interpretation of the tense calculus within the l-calculus as "a metaphysical explanation of what we mean by *is*, *has been* and *will be*": the l-calculus is not "metaphysically fundamental". His reason is that F(Socrates is sitting down) means ‘It is *now* the case that it will be the case that Socrates is sitting down’, and there is no genuine way of representing the indexical ‘now’ in the l-calculus (the free variable z is ‘a complete sham’). He continues: "If there is to be any ‘interpretation’ of our calculi in the metaphysical sense, it will probably need to be the other way round; that is, the l-calculus should be exhibited as a logical construction out of the PF-calculus rather than *vice versa*." This idea of the primacy of the tense calculus over the l-calculus - or, as he was later to put it, of McTaggart's A-series over the B-series - was to become a central and distinctive tenet of his philosophy. Prior's thesis is perhaps even more radical in its application to modal logic: the language of possible worlds is to be interpreted in terms of a language with modal operators and not - as is popularly held - *vice versa*. These issues form the theme of his final book *Worlds, Times and Selves* (edited by Kit Fine).

The text of the Wellington address was not published until 1958 (in the journal *Franciscan Studies*, under the title ‘The Syntax of Time-Distinctions’). It was the 1956 John Locke lectures and the ensuing book *Time and Modality* (published in 1957) that brought Prior's discoveries in tense and modal logic before a wider audience. A number of logicians - notably Thomas, Geach, Lemmon, Meredith and Kripke - took an immediate interest in Priorean modal logic, in particular his Diodorean system and his system Q, a multivalued logic admitting the existence of contingent beings. Less immediate attention was paid to his tense logic. The bibliography of the subject in Prior's 1968 volume *Papers on Time and Tense*

reveals that up until 1965 the only publications in the field were either by Prior himself or were reviews of his work (chiefly of *Time and Modality*). Yet a momentum was slowly gathering.

At a colloquium on modal and many-valued logics held in Helsinki in 1962 Hintikka proposed a tense-logical construal of his possible worlds semantics, maintaining that ‘if we do not want to tie our logic to old-fashioned physics, we are undoubtedly wiser if we ... no longer require that the alternativeness relation (in this case it could perhaps be more appropriately termed "futurity relation") effect a linear ordering’ (1963: 76). (Prior had happily tied his 1954 l-relation to ‘old-fashioned physics’. He made it clear that he did not think much of the view of time embodied in twentieth century physics (1996b: 49-51).) A pupil of von Wright, Hintikka had been stimulated by the latter's proposals for the wide application of modal logic (see the next section) and had come to appreciate the possibility of applying modal notions to the study of the logic of time before he read of Prior's sophisticated work in *Time and Modality* (which he reviewed in 1958). Hintikka was perhaps the first to stress the importance of a semantical approach to the tenses. During the early 1960s Hintikka travelled regularly between Helsinki and California. His ideas on tense influenced a number of logicians working in California, in particular Dana Scott.

Also in 1962, Scott gave a lecture on tense logic in Amsterdam. Among his audience was Hans Kamp, then an undergraduate. Scott's work on tense logic was one aspect of his study of the semantics of natural language, which he pursued in close collaboration with Richard Montague. Scott was aware of Prior's work, and was also influenced in his understanding of tense by Reichenbach, who had been a powerful figure at UCLA until his death in 1953. (Prior himself was critical of Reichenbach's analysis of the tenses, and described it as having been ‘in some ways a hindrance rather than a help to the construction of a logic of tenses’ (Prior 1967: 13, Reichenbach 1948).) Scott's tense logic was rather different in style from Prior's. Scott established the completeness and decidability of various axiomatic tense logics. He also showed that the temporal predicate logic of the reals is non-axiomatisable. His work in tense logic is cited widely but remains unpublished. Prior learned of Scott's work in a letter from Lemmon dated January 1964. (Lemmon had left Oxford in 1963 for Claremont, near Los Angeles. Scott was then at Stanford.)

In 1965 Prior visited California for several months, as Flint Professor of Philosophy at UCLA. For the first time Prior found himself among a group of enthusiasts for tense logic. Shortly after the visit ended he was to write: "I suppose that California is the most logically mature place in the world, and now that the logic of tenses is pursued so widely and so vigorously there, its raw pioneering days can be considered over" (1967: vi). When Prior arrived at UCLA Nino Cocchiarella was just completing a Ph.D. thesis on quantified modal and tense logic under Montague's supervision (‘Tense and Modal Logic: A Study in the Topology of Temporal Reference’). Cocchiarella's interest in the philosophy of time had initially been aroused by Reichenbach's work on space and time but it was his acquaintance with Prior's *Time and Modality* that swept him into tense-logical research. (Only later did he learn of Scott's work.) Prior's visit coincided with Hans Kamp's arrival at UCLA as a graduate student. Kamp attended Prior's lectures on tense logic in his first semester and became deeply interested in the subject. These lectures led more or less directly to the topic of Kamp's Ph.D. thesis, written under Montague's supervision and entitled ‘On Tense Logic and the Theory of Order’ (1968). In Kamp's work the development of tense

logic achieved a new level of formal sophistication. Segerberg, too, had just arrived in California, to study under Scott at Stanford. (Segerberg had become interested in tense logic in Finland in 1964 at a series of summer seminars given by von Wright, who was independently pursuing a tense logic that had arisen from his study of the logic of action and which was later shown to be equivalent to a system Prior had discussed in *Time and Modality* (Prior 1957: 23-4; see von Wright 1965 and Segerberg 1967, 1989).) In December of 1965 Scott delivered his famous talk to the Hume Society at Stanford entitled ‘The Logic of Tenses’. A multilith of Scott's handwritten notes for this talk has been circulating ever since among tense logicians. Four days later Prior himself addressed the Society, again on tense logic. It was in this fecund atmosphere that Prior completed the manuscript of his book *Past, Present and Future*, which remains to this day one of the most important references in the field.

The years 1965-7 saw the publication of work in tense logic by &Aqvist, Bull, Clifford, Cocchiarella, Garson, Geach, Hamblin, Luce, Makinson, Rescher, Segerberg, von Wright - and, of course, Prior. In a little over a decade Prior's invention had become an internationally pursued branch of logic.

Prior always had a firm belief that his tense logic would one day find useful application in other disciplines (possibly in mathematical physics, he thought). When the outside demand for tense logic did come it was from computer science. An early and influential application was by Pnuelli, who employed tense logic in formal reasoning about the behaviour of concurrent programs (Pnuelli 1977). (A concurrent program is one that governs the behaviour of a number of interacting processors running in parallel.) Pnuelli is sometimes mistakenly credited with having originated tense logic but in fact he first learned of it from the classic volume ‘Temporal Logic’ by Rescher and Urquhart (1971) (Ohrstrom and Hasle 1995: 344). This volume is dedicated to Prior and is an elegant introduction to his work.

Prior would not have been completely surprised to learn how useful tense logic is proving to be in computer science. He himself took little interest in computing beyond including material on elementary boolean circuit theory in his undergraduate lectures, but a number of the logicians with whom he was in touch were more deeply involved (Dov Gabbay and Dana Scott, for instance). Through others Prior knew something of the potential. He wrote "There are practical gains to be had from this study too, for example in the representation of time-delay in computer circuits" (1996a: 46). In *Past, Present and Future* he remarked concerning logics of discrete time that their usefulness "does not depend on any serious metaphysical assumption that time *is* discrete; they are applicable in limited fields of discourse in which we are concerned only with what happens next in a sequence of discrete states, e.g. in the workings of a digital computer" (1967: 67). Other logics from the group that he and von Wright pioneered are also finding computational applications, for example epistemic logic in Artificial Intelligence and knowledge-base engineering, and the logic of action in programming theory.

It is noteworthy that two of the major forces in the genesis of these software technologies were a love of ancient and medieval logic and a concern to make conceptual room for freedom of the human will. Only people who know little of the history of ideas will find any incongruity here. Would that those who now control and administer the funding of university research were less unaware of the oblique ways in which idea gives rise to idea.

Work on Modal Logic

Prior's own interest in modal logic arose chiefly from his study of the ancients. His earliest written piece on modal logic, the penultimate chapter of his manuscript *The Craft of Formal Logic* (completed in 1951) is largely historical in nature, with discussions of Aristotle, Peter of Spain, John Wallis, the *Port Royal Logic*, Isaac Watts' *Logick*, Hume and Mill on natural necessity, de Morgan, Whately, Aldrich. One of his conclusions, significant for his later work, is that "[t]here is everything to be said ... for the ... view that we may not only use devices developed in the study of quantity to throw light on modality, but also *vice versa*" (p.747). One of the most distinctive features of his mature philosophy was the view that quantification over possible worlds and instants is to be interpreted in terms of modality and tense, which constitute primitive notions - a view which he held in tandem with the belief that the study of such quantifications could usefully illuminate the study of modality and tense (as in his own U-calculi, described below). The chapter contains brief comparisons of the symbolic notations of Lukasiewicz, Feys and Lewis, but Prior makes very little use of the symbols he describes. At one point he explains that symbolic notation can be used to good advantage to bring out the difference between ‘Everything has something which is F to it’ and ‘There is something which is F to everything’. Probably Prior was just beginning to appreciate the power of the new symbolism to express the subtle distinctions demanded by his subject matter.

Early in 1951 Prior read von Wright's article ‘Deontic Logic’, and the penultimate chapter of *The Craft* contains a cameo discussion of this topic. Von Wright's influence is also clear in the paper Prior read in August of that same year to the AAP Conference in Sydney, entitled ‘The Ethical Copula’. Here Prior discusses and defends the parallel von Wright drew in ‘Deontic Logic’ between moral words and modal words. No doubt Prior found in deontic logic a significant connection between his existing interest in ethics and his fast-developing interest in modal logic.

Prior's reading of von Wright reinforced in his mind an idea that he had come across in Peter of Spain, Isaac Watts and the *Port Royal Logic*, an idea that was to be of considerable importance for his own future work. What von Wright calls the ‘alethic’ modes - necessity, possibility, impossibility and contingency - are members of an extended group of concepts that includes the epistemic modes (‘it is known that’, ‘it is not known to be false that’, etc.), the doxastic modes (for example ‘it is believed that’), and the deontic modes (such as ‘it is permitted that’ and ‘it is obligatory that’). In *The Craft* Prior also lists Watts' ‘it is written that’ and ‘it is said that’, noting that "one could think of innumerable others" (p.749). Later von Wright was to draw attention to what may be called the agentive modes: ‘the agent brings it about that’, ‘the agent makes it true that’, and the like (von Wright 1963). Prior introduces the collective term ‘quasi-modals’ for the non-alethic modes (p.749) and remarks, accurately, that "there is a hint of a large field here" (p.752). He was later to refer to his own tense operators as quasi-modal operators (1968: 138). By the time he wrote *Formal Logic* he was advocating the study of "the general modal form ‘It is -- that p’; ... as a distinct propositional form", observing that "this field has not been much cultivated" (1955a: 218). Between them Prior and von Wright pioneered the now much investigated field of general intensional logic, as it may be called, in which the syntax, and latterly the semantics, developed for the study of the alethic modalities is used in the analysis of a wide range of

quasi-modal concepts. Von Wright's deontic logic and Prior's tense logic were the first major successes in this field. Another has been the logic of action or the logic of the agentive modes.

Prior was convinced that no satisfactory metalinguistic analysis can be given of sentences having the general modal form ‘It is -- that p’. In *Formal Logic* he writes "It is quite plain, for example, that I am not talking about the sentence ‘Socrates is dead’; when I say ‘I wish that Socrates were dead’; " (1955a: 219). In *Time and Modality* he reiterates the point, now in connection with the tenses: "‘Professor Carnap will be flying to the moon’; ... is quite obviously a statement about Professor Carnap, and quite obviously not a statement about the statement ‘Professor Carnap is flying to the moon’" (1957: 8). What, then, is the semantic value of an expression replacing p in a sentence of the general modal form ‘It is -- that p’? Certainly not a truth value, as is the case with the standard extensional propositional calculus, for substituting a different expression with the same truth value into the sentence of the form ‘It is -- that p’ may alter the truth value of the latter sentence. Prior's answer - and in a sense it amounts to a rejection of the question - is that modal functions take propositions as arguments, but propositions are logical constructions. All sentences containing the word ‘proposition’ - including such sentences as ‘A modal operator expresses a function from propositions to truth values’ - mean no more and no less than sentences which contain neither that word nor an equivalent. In essence Prior's view is that there are intensional contexts but no intensions. For the last six years of his life Prior worked on a book that was to give systematic expression to his views on propositions. The incomplete manuscript, which Prior had entitled *Objects of Thought*, was published posthumously in 1971.

Of the four technical papers that marked the explosive beginning of Prior's career as a formal logician in 1952, two concern modal logic. ‘Modality De Dicto and Modality De Re’ is a discussion of this distinction as it appears in Aristotle, Ockham and Peter of Spain together with a comparison of these earlier views with those of von Wright in *An Essay on Modal Logic*. ‘In What Sense is Modal Logic Many-Valued?’ proposes an interpretation of Lukasiewicz's four-valued matrices for modal logic. This paper marked the beginning of Prior's study of Lukasiewicz's work on modality. Thereafter he read Lukasiewicz widely - even material in Polish, of which he said "the symbols are so illuminating that the fact that the text is incomprehensible doesn't much matter". In the Preface to *Time and Modality* he wrote "[W]hile I differed radically from the late Professor Lukasiewicz on the subject of modal logic, my debt to him will be obvious on almost every page".

Prior's detailed contributions to the development of modal logic are legion. At least one aspect of his work has not received the recognition it deserves. Prior and his collaborator Carew Meredith invented crucial elements of the possible worlds semantics for propositional modal logic several years ahead of Kripke, including the all-important binary relation which opens the way to modelling systems of different strengths. (Meredith was a lecturer in mathematics at Trinity College, Dublin, whose interest in logic was stimulated by the arrival of Lukasiewicz in Dublin shortly after the war.)

The invention is foreshadowed in the penultimate chapter of *The Craft*.

> For the similarity in behaviour between signs of modality and signs of quantity, various

> explanations may be offered. It may be, for example, that signs of modality are just ordinary quantifiers operating upon a peculiar subject-matter, namely possible states of affairs ... It would not be quite accurate to describe theories of this sort as ‘reducing modality to quantity’. They do reduce modal *distinctions* to distinctions of quantity, but the variables to which the quantifiers are attached retain something modal in their signification - they signify ‘possibilities’, ‘chances’, ‘possible states of affairs’, ‘possible combinations of truth-values’, or the like. (pp. 736-7.)

As sources for this idea Prior cites John Wallis (a seventeenth century logician) and the account of logically necessary and logically impossible propositions given by Wittgenstein in the *Tractatus* (p.737). Interestingly, he mentions Carnap only in a footnote: "Professor Carnap has a similar definition of logical necessity in terms of what he calls ‘state-descriptions’" (ibid). Prior does not refer to, and presumably had not at that time read, Carnap's 1946 paper ‘Modalities and Quantification’, which attempted a semantics for quantified S5 in terms of state-descriptions. (A state-description is a class of sentences satisfying certain conditions. Each state-description represents a possible state of affairs.) Carnap too cites the *Tractatus* account of modal propositions as his inspiration (1946: 47). Prior goes on to defend his account of modality as quantification over possible states of affairs against various alternatives, for example the Andersonian account, according to which ‘Every table here is necessarily brown’ means ‘There is a property which every table here in fact possesses, and of which it is true that everything that possesses it is in fact brown’. (John Anderson, Professor at the University of Sydney, was a leading figure in the development of philosophy in Australasia.)

In 1956 Prior wrote up his and Meredith's formal work on what he later described (1962a: 140) as the ‘logic of world-accessibility’, in a paper entitled ‘Interpretations of Different Modal Logics in the "Property Calculus"’ (Meredith and Prior 1996). It carries the attribution ‘C.A.M., August 1956; recorded and expanded A.N.P.’. Prior circulated the paper in mimeograph form. He mentions it in *Past, Present and Future* (1967: 42-5) and in his 1962 articles ‘Possible Worlds’ and ‘Tense-Logic and the Continuity of Time’. This paper is one of the earliest to employ a binary relation between possible states of affairs in order to discriminate between S5 and weaker systems. (Carnap's 1946 paper concerned only S5 and contained no such relation.)

The property calculus is essentially a variation of Prior's 1954 l-calculus described above. In the l-calculus tense-modal propositions are treated as predicates expressing properties of dates, and quantification theory is supplemented with various special axioms for a binary relation ‘l’ taking dates as arguments. In the modal version of the calculus sentences of modal logic are treated as if they express properties of certain objects a, b, c, etc. Objects are related by a binary relation U. (Prior and Meredith supply no account of what a formula of form ‘Uab’ might express.) The following definitions of necessity L and possibility M are given (‘pa’ indicates that object a has the property expressed by the sentence p):

$$(Lp)a = (b)(Uab \rightarrow pb)$$

$(Mp)a = (\exists b)(Uab \,\&\, pb)$.

The calculus consists of ordinary quantification theory supplemented by these definitions, together with certain axioms governing the relation U, and the following clauses:

$(-p)a = -(pa)$

$(p \rightarrow q)a = (pa) \rightarrow (qa)$.

It is implied that a modal proposition A is to be called a theorem of the calculus if and only if Aa is provable for an arbitrarily chosen object a.

Axioms for U are selected from a list containing (amongst others):

1. Uaa (U is reflexive)

2. Uab → (Ubc → Uac) (U is transitive)

3. Uab → Uba (U is symmetrical).

(Axiom 2 is also present in the l-calculus.) Prior and Meredith establish that the distribution principle L(p → q) → (Lp → Lq) is a theorem in the absence of any special axioms for U; that Lp → p is a theorem if axiom 1 is imposed; that axiom 2 gives the S4 principle Lp → LLp; and that 2 together with 3 give the S5 principle MLp → Lp. (Their approach is proof-theoretic in its basic orientation and they offer no completeness results.) In 1962a and 1962b Prior extends the approach to systems between S4 and S5 and systems independent of S4 between T and S5.

As previously remarked, the idea that the variables of quantification of the calculus should range over possible states of affairs or possible worlds is present in *The Craft*. In 1960, following a suggestion by Geach, Prior began thinking of U as a relation of *accessibility* between worlds. Prior tells us that Geach cashed out the notion of 'reaching' one world from another in terms of 'some dimension-jumping vehicle dreamed up by science fiction' (1962b: 36; see also 1962a: 140). (Geach referred to the whole business as 'Trans World Airlines'.) With this interpretation of U to hand, the property calculus can be viewed as treating (Lp)a - or 'Necessarily-p in world a' - as short for 'p is true in all worlds accessible from a'. Lemmon, in a draft of material intended for his and Dana Scott's projected book 'Intensional Logic', mistakenly credits Geach with the idea that the binary relation 'may be intuitively thought of as a relation between possible worlds'. In a letter to Scott, written after Lemmon's death in 1966, Prior remarked: "What Geach contributed was not the interpretation of [U] as a relation between worlds (God knows when *that* started), but the interpretation of [U] as a relation of accessibility". When Prior says "God knows when *that* started" he is presumably referring to the idea that the 'objects' of the calculus be regarded as possible worlds. Prior was right to think that the history of this idea is a tangled one. Priority is often assigned to Leibniz, but scholars have now traced the idea back to Duns Scotus and William of

Ockham (Knuuttila 1993).

It seems that the binary relation first made its appearance in a 1951 article by Jonsson and Tarski, ‘Boolean Algebras with Operators’. In their Theorem 3.14 they establish that every closure algebra is isomorphic to an algebraic system formed by a set and a reflexive and transitive relation between its elements; their Theorem 3.5 considers also a symmetry condition. In hindsight these theorems (which explicitly concern boolean algebras, of course) can be viewed as in effect a treatment of all the basic modal axioms and corresponding properties of the accessibility relation. Concerning this article Saul Kripke has remarked:

> Had they known they were doing modal logic, they would have had the completeness problem for many of the modal propositional systems wrapped up, and some powerful theorems. Mathematically they did this, but it was presented as algebra with no mention of semantics, modal logic, or possible worlds, let alone quantifiers. When I presented my paper at the conference in Finland in 1962, I emphasized the importance of this paper. Tarski was present, and said that he was unable to see any connection with what I was doing!

During the next eight years the binary relation was reinvented by a number of logicians. Prior, in his address to a conference in Wellington in 1954, seems to have been the first to use the binary relation in an explicitly tense-modal context. Other landmarks were an address by Montague to a conference held at UCLA in 1955, Prior and Meredith's property calculus of 1956, and Kanger (1957), Hintikka (1957, 1961) and Kripke (1959a, 1959b, 1963). Kripke was familiar with Kanger's work involving the binary relation at the time he obtained his own results. Kanger himself had read the 1951 paper by Jonsson and Tarski and he describes his results as similar to theirs (Kanger 1957: 39). My forthcoming paper ‘Possible Worlds: the Pre-Kripkean Era’ gives a fuller account of the history of the possible worlds semantics.

It was through reading Prior's paper ‘Modality and Quantification in S5’ in 1956 that Kripke first became interested in modal logic. He was at this time still a schoolboy, working on logic in almost complete isolation in Omaha, Nebraska. In 1958 he read *Time and Modality* and was impressed by the parallel Prior drew between tense and the alethic modalities. (At almost exactly the same time Prior was reading Kripke's first paper, ‘A Completeness Theorem in Modal Logic’, in his capacity as referee for *The Journal of Symbolic Logic*.) Kripke suspects that it was his reading of *Time and Modality* that first interested him in the problem of treating variable domains (a constant domain is assumed in ‘A Completeness Theorem in Modal Logic’). Kripke worked on Prior's idea that variable domains might lead to truth-value gaps even at the level of propositional logic, although he did not pursue this approach in his published material. (This idea was the motivation for Prior's system Q.) Kripke thinks it probable that it was Prior's work on many-valued matrices in *Time and Modality* which gave him the idea that a possible worlds model can be converted to a many-valued matrix (an idea he developed in his 1963 paper ‘Semantical Analysis of Modal Logic I: Normal Modal Propositional Calculi’).

Kripke wrote to Prior (September 3, 1958) pointing out an error in *Time and Modality*: contrary to Prior's claim, the Diodoran matrix (1957: 23) is not characteristic of S4. In his letter Kripke gave a characteristic matrix for S4 involving the idea that in a non-deterministic universe time branches into the future. He wrote:

> [I]n an indetermined system, we perhaps should not regard time as a linear series, as you have done. Given the present moment, there are several possibilities for what the next moment may be like - - and for each possible next moment, there are several possibilities for the moment after that. Thus the situation takes the form, not of a linear sequence, but of a ‘tree’.

This is essentially no more than a tensed interpretation of Kripke's relational semantics for S4, as he himself points out in the letter. Prior was excited by the letter and passed it on to Ivo Thomas and John Lemmon. Kripke wrote again on October 13, 1958. (The letters may still be seen in the Bodleian Library, Oxford. They are discussed in Ohrstrom and Hasle (1993).)

Prior's Life

In 1932, at the age of 17, Arthur Prior left his home town, sleepy Masterton in the North Island of New Zealand, and enrolled at the University of Otago. The son of a doctor, Prior's initial intention was to study medicine. He was soon beckoned away by philosophy, in which he gained a B.A. in 1935. It was John Findlay, then Professor of Philosophy at Otago, who introduced Prior to logic. A contemporary of Gilbert Ryle and William Kneale, Findlay himself had studied at Graz and at Oxford; his influential book *Meinong's Theory of Objects* was published during Prior's second year at Otago. Under Findlay's direction Prior cut his teeth on W.E. Johnson's classic text *Logic* and studied the 18th century British moralists. It was Findlay who first interested Prior in the history of logic. In 1949 Prior wrote of him ‘I owe to his teaching, directly or indirectly, almost all that I know of either Logic or Ethics’ (1949: xi) and he was later generously to describe Findlay as ‘the founding father of modern tense-logic’ (1967: 1).

Prior's M.A. thesis, in which he criticised subjectivist and formalist approaches to logic, was awarded only a second by the external examiner. Fortunately Findlay knew a budding logician when he saw one and secured Prior an assistant lectureship at Otago. During 1937 Prior gave courses on logic, ethics, and probability theory. In December of that year his first published paper - arguing that a nation is a logical construction out of individuals - appeared in the *Australasian Journal of Psychology and Philosophy*.

At this point Prior temporarily abandoned his academic career and spent three bohemian years wandering in Britain and Europe. He returned to New Zealand at the end of 1940, and on emerging from the air force in 1945 he applied for a vacant lectureship at Canterbury University College in Christchurch. By now he had a further three articles in the *Australasian Journal of Psychology and Philosophy* (‘Can Religion be Discussed?’, ‘The Meaning of Good’ and ‘The Subject of Ethics’) and with a strong recommendation from Findlay Prior got the job. He started work in February 1946. (The vacancy Prior filled was created by the departure from New Zealand of Karl Popper. Prior and Popper were never

colleagues. Apart from Prior's attendance at some of Popper's Workers' Educational Association lectures in 1943 there was no contact between the two men.)

At Canterbury Prior was thrown entirely on his own resources, being as he put it "the only philosopher about the place". He bore the responsibility for providing a broad and balanced philosophy curriculum, yet his own formal education in philosophy had stopped short nine years previously. Prior's one recourse in the face of isolation was to read, and read he did. In logic he began by returning to W.E. Johnson. Next came J.N. Keynes's *Studies and Exercises in Formal Logic* and then (in his own phrase) he got stuck into *Principia Mathematica*. He learned a lot about the history of the subject from Peirce, whom he found "unexpectedly magnificent". An important discovery, in 1950, was Bochenski's *Precis de Logique Mathematique*. Prior was fascinated by the ‘very neat symbolic notation’ due to Lukasiewicz, and before long he turned his back completely on the more usual Peano-Russell notation. Bochenski was later to describe Prior as even more of a ‘CCCC-logician’ than he was himself. (In Lukasiewicz's parenthesis-free notation Cpq is written for ‘If p then q’, Kpq for ‘Both p and q’, Apq for ‘Either p or q’, Epq for ‘If and only if p then q’, Np for ‘Not p’.) Lukasiewicz's own *Aristotle's Syllogistic* and Tarski's *Introduction to Logic* soon followed. By now the logic bug had well and truly bitten. Prior saw from the work of the Poles that formal precision is possible in philosophy and this delighted him. The upshot of Prior's reading for the curriculum was that his students learned Aristotelian and medieval logic, using Polish notation and with Bochenski's *Precis de Logique Mathematique* as a text. "Despite the language difficulty, I have found this a first-class textbook to accompany lectures to New Zealand students", he declared (1952c: 35).

An exuberant, playful man of seemingly inexhaustible vitality, Prior made an excellent teacher. He had no trace of pomposity or pretension. His students appreciated the friendly welcome they would receive at his home, not to mention his relaxed attitude toward the administrative paraphernalia of roll-taking and the like. In those days Canterbury University College was a formal, stuffy place and Prior was a breath of fresh air for his students. In a milieu where jacket and tie were the norm even in a sweltering New Zealand summer, Prior would lecture in baggy khaki shorts and roman sandles. Jim Wilson recalls the friendly informality of Prior's first-year classes:

> The strained precision of clock time was alien to him, so he was usually late for his own lectures (or anyone else's for that matter - he was very egalitarian about it). But he almost always turned up eventually, thinning hair blown vertical by his dash on his bike when he remembered the time. He would pull cycle clips off his trousers and plonk an ancient shopping bag on the desk in front of him. Out of this bag would come ... a cabbage, a bunch of carrots, a loaf of bread, a bottle of milk ... until, always at the bottom, he would find the book he was looking for. Back into the bag went the rest of the goodies, then he would look up at us, apologise for being late if he was more than usually so, and ask: "Now where were we last time?" Someone in the front row would consult her or his notes - Arthur couldn't as he never had any - and would say "You were just dealing with such and such." "Ah yes, thank you" Arthur would respond, and forthwith launch into an extempore exposition which followed on perfectly from the previous session and was beautifully structured and clear even though he was just thinking along with us. And of course we

> could stop him and ask for clarification or elaboration at any time, without in the slightest affecting the overall structure and direction of his thoughts.

Soon after his discovery of *Precis de Logique Mathematique* Prior wrote to Bochenski in Fribourg and then, a little later, to Lukasiewicz in Dublin. He was excited to receive replies. "We are, all of us, very isolated, being few and scattered", wrote Bochenski. "It is a real pleasure to hear that a Colleague so far away is interested in the same problems you are working at and that he finds one's little writings may be of some use." Thus began Prior's voluminous correspondence with logicians the world over. There were other ways, too, in which his isolation lessened. In 1951 he met and became friends with John Mackie and Jack Smart, at a conference in Sydney. This was Prior's first experience of being among a large gathering of philosophers and Mary Prior describes the conference as his ‘entry into a wider world’. In the same year George Hughes was appointed to the Victoria University of Wellington. Prior and Hughes had to make the most of their all-too-infrequent meetings, sometimes talking until the birds woke. Prior was fortunate in having a number of excellent students during these early years, among them Jonathan Bennett, Ronald Butler and (a little later) Robert Bull. For Prior they were oases in the desert. In 1952 he gained an assistant lecturer, Sandy Anderson. The following year philosophy became a department in its own right and Prior was made Professor.

1949 saw the publication of Prior's first book, a slim but potent volume entitled *Logic and the Basis of Ethics*. It was published by the Clarendon Press and soon became prominent in Oxford. Austin liked it and Ryle approved of "Prior's complete lack of mugwumpery". In the Introduction Prior explains that by the ‘logic of ethics’ he means "not a special kind of logic, nor a special branch of logic, but an application of it", and the book is a vigorous examination of the arguments of each side in the naturalism/anti-naturalism debate.

Logic and the Basis of Ethics contains no symbolism, and Prior's phrase ‘the logic of ethics’ is little more than a battle cry. The few technical concepts that are introduced all pertain to syllogistic logic. It was not until 1952 that Prior began publishing papers in symbolic logic - four of them, suddenly, in the same year. At the unusually late age of 38 Prior had become a formal logician. He wrote these papers while completing the manuscript of what was intended to be his second book, *The Craft of Formal Logic*. (The manuscript of *The Craft of Formal Logic* is deposited in the Bodleian Library, Oxford.) This began life in 1949 as a Dictionary of Formal Logic, but at the advice of the Clarendon Press Prior soon switched to a more orthodox format. His logical interests veered sharply while he was writing *The Craft*. To sixteen chapters on the logic of categoricals, hypotheticals, terms and relations are added, almost as an afterthought, one on modal logic and one on the axiomatic method. Prior finished the manuscript in December 1951 and sent it to the Clarendon Press; fourteen months later they wrote agreeing to publish the book if Prior would both shorten it and give greater emphasis to modern logic. He undertook to make the changes but ended up writing a completely different book. This was finally published in 1955 with the title *Formal Logic*; it ran into a second edition in 1962. Parts of *The Craft* not absorbed into the later work were published posthumously under the title *The Doctrine of Propositions and Terms*.

Steeped in Polish notation and the axiomatic method, *Formal Logic* typifies Prior's mature work. It teaches, enthusiastically yet without fuss, that there was life - fascinating life - before the here and now

of logic. What Prior once wrote admiringly of Lukasiewicz is no less true of Prior himself: ‘having done very distinguished work as a mathematical logician in the modern style, [he] is at the same time interested in the history of his subject ... and contrives both to use modern techniques to bring out more clearly what the ancients were driving at, and to learn from the ancients useful logical devices which the moderns have in general forgotten’ (1952c: 37).

After Findlay, Lukasiewicz was the greatest single influence on Prior's development as a logician. Prior's 1952 review article ‘Lukasiewicz's Symbolic Logic’ is one of the first papers in which he makes extensive use of symbolism. (He discusses Lukasiewicz's book *Aristotle's Syllogistic From the Standpoint of Modern Formal Logic* (published in 1951) and two articles, ‘The Shortest Axiom of the Implicational Calculus of Propositions’ and ‘On Variable Functions of Propositional Arguments’.) Prior seems to have first learned of Lukasiewicz's work through Bochenski's writings (Bochenski was a pupil of Lukasiewicz). Lukasiewicz had devised an axiomatic treatment of Aristotle's reduction of the imperfect syllogistic moods to those of the first figure, which Prior encountered in Bochenski's *Precis de Logique Mathematique* (published in 1949). This enchanted Prior. He was taking his students through the derivations as early as 1951, and he summarises Lukasiewicz's system in the final chapter of *The Craft.* Throughout this chapter he makes extensive use of Lukasiewicz's symbolic notation. It was Lukasiewicz's axiomatic treatment of traditional logic that fully brought home to Prior the power of modern symbolic methods. Moreover it was probably his reading of Lukasiewicz that made clear to him the fundamental importance of propositional logic. "It seems that Aristotle did not suspect the existence of another system of logic besides his theory of the syllogism", Lukasiewicz had written, "[y]et he uses intuitively the laws of propositional logic ..." (1951: 49). (Lukasiewicz's axiomatisation of the syllogistic incorporates his own three-axiom formalisation of propositional logic (1951: 80).) In his review Prior quotes approvingly Lukasiewicz's assertion that "the logic of the Stoics, the inventors of the ancient form of the propositional calculus, was much more important than all the syllogisms of Aristotle" (1951: 131). In *The Craft* propositional logic is barely mentioned until the final chapter, whereas *Formal Logic* begins with a thorough introduction to the subject. On page 3 of *Formal Logic* Prior states that the logic of propositions is "basic, and the rest of logic built upon it". Prior's interest in economical bases for propositional and pure implicational logics, initially aroused by his study of Peirce, was stimulated by Lukasiewicz's article ‘The Shortest Axiom of the Implicational Calculus of Propositions’ and the opening chapters of *Formal Logic* draw heavily on Lukasiewicz's work in this area.

In 1954 Gilbert Ryle visited New Zealand. He brought Prior an invitation to visit Oxford and deliver the John Locke lectures. Prior arranged a twelve month leave of absence from Canterbury and arrived in Oxford at the beginning of 1956. Rather quickly a small group began to form around him: Ivo Thomas, John Lemmon, Peter Geach. (These meetings with Prior were Lemmon's first introduction to modal logic.) Hughes summarises the news of him that was arriving back home: "this wild colonial boy just hit Oxford and started to gather around him the main people [interested in] logic, and he started to organise a lot of parties, almost, for the serious doing of logic." Prior kitted out his tiny rented flat with a toyshop blackboard and held open house. On Mondays during Hilary and Trinity terms Prior lectured on modal logic, his great passion, and on tense logic, his great invention. The lectures were published the following year, under the title *Time and Modality*.

In the summer break following the John Locke lectures Prior organised a Logic Colloquium in Oxford. In Britain in the 1950s logic was deeply out of fashion and its practitioners were isolated and somewhat demoralised. As Prior wrote shortly after the Colloquium "There *are* logicians in England and Ireland; but it must be admitted that they are somewhat scattered, and so far as I could gather they had never had any general get-together" (1956b: 186). Prior's Colloquium brought together Lemmon, Thomas, Geach, M. Kneale, W.C. Kneale, Lewy, Smiley, Bennett, Lejewski, M.W. Dick, Faris, Nidditch, Carew Meredith, David Meredith, and others. It was all a huge success, and the Colloquium became a regular fixture. Through his John Locke lectures, the Colloquium, and his numerous visits around the country, Prior helped to revitalise British logic. The group he left behind saw similarities between themselves and the close-knit group of researchers that existed in Warsaw before 1939.

Prior's heart may have been heavy as he journeyed back to New Zealand. After twelve months of logical companionship on a grand scale, life at Canterbury must have seemed a bleak prospect. He was seething with enthusiasm for logic and threw himself once more into a massive correspondence, but it could no longer satisfy him. Prior pined. When the offer arrived of a newly established second chair at the University of Manchester he snatched it up. Prior left New Zealand in December 1958.

He was at Manchester for seven years. In 1966 Anthony Kenny recommended him for a fellowship at Balliol. The move would mean a drop in both status and salary, not to mention an increase in teaching, but Prior did not hesitate. His sabbatical in Oxford had been one of his happiest years. ‘This is the good life’, he told George Hughes once he was settled in at Balliol. He felt he simply belonged. Prior soon built up a reputation for being one of the best teachers in Oxford - though his students were sometimes surprised to be given eighteenth century moralists to read instead of books by the currently fashionable.

Just before his departure from Manchester Prior told Tom Richards, a visiting New Zealander, that he was going to Oxford with a mission. Prior's own work was an exemplary fusion of philosophy and logic, and he went to Oxford with the intention of interesting the mathematical logicians in philosophy and the philosophers in mathematical logic. The time was right; and Prior spared no energy in preaching his message:

> [F]ormal logic and general philosophy have more to bring to one another than is sometimes supposed. I do not mean by saying this to underrate the work of those who have explored the properties of symbolic calculi without any concern as to what they might be used to mean ... Nor do I mean to underrate what recent philosophers have done in the way of exploring the obstinate and intricate ‘logic’ embedded in common discourse, even when they have not derived or sought to derive anything like a calculus from it ... But these activities are, or can be, related to one another very much as theory and observation are in the physical sciences; and I must confess to a hankering after well-constructed theories which much contemporary philosophy fails to satisfy. (1957: vii.)

Prior did not live to enjoy the *entente cordiale* between philosophy and logic that he helped usher in. His health began to let him down during his second year at Balliol. He was found to have both angina

pectoris and polymyalgic rheumatism. During the autumn of 1969 the rheumatism grew steadily worse. He was at this time on sabbatical at the University of Oslo. The pain left him with no zest for work. He dutifully gave his weekly seminars and spent the remainder of his time brooding savagely on how painful it was to do such elementary things as put on a coat. His hosts made him an appointment with a rheumatologist, who prescribed cortisone. In a letter written a few days later, and a few days before his heart failed, Prior described himself as one of the miracles of modern medicine. "I've been sleeping well ... running up and down stairs ... I can stand on one leg and put a sock on the other (first time for months) ... they've got me cured now and I'm fine."

Actualism

To understand the thesis of actualism, consider the following example. Imagine a race of beings -- call them ‘Aliens’ -- that is very different from any life-form that actually exists anywhere in the universe; different enough, in fact, that no actually existing thing could have been an Alien, any more than a given gorilla could have been a fruitfly. Now, even though there are no Aliens, it seems intuitively true that there could have been such things. After all, life could have evolved very differently than the way it did in fact, differently enough, at least, that other kinds of things might have existed. So why is it true that there could have been Aliens when in fact there are none, and when, moreover, nothing that actually exists could have been an Alien?

To answer this question, a philosopher should try to identify the special features of the world that are responsible for the truth of claims about what could have been been the case. One group of philosophers, the *possibilists*, offer the following answer: ‘It is possible that there are Aliens’ is true because there are in fact individuals that could have been Aliens. By hypothesis, however, such individuals are simply possible and not actual. No actually existing thing could possibly have been an Alien. Hence, the truth of ‘It is possible that there are Aliens’ is, according to possibilism, grounded in the fact that there are possible-but-nonactual Aliens, i.e., things that are not actual but which could have been, and such that, moreover, if they had been actual, they would have been Aliens.

Actualists reject this answer; they deny that there are any nonactual individuals. Actualism is the philosophical position that everything there is -- everything that can be said to exist in any sense -- is *actual*. Put another way, actualism denies that there is any kind of being beyond actuality; to be is to be actual. Actualism therefore stands in stark contrast to possibilism, which, as we've seen, takes the things there are to include possible but non-actual objects.

Of course, actualists will agree that there could have been Aliens. Actualism, therefore, can be thought of as the metaphysical theory that attempts to account for the truth of claims like ‘It is possible that there are Aliens’ without appealing to any nonactual objects whatsoever. What makes actualism so philosophically interesting, is that there is no obviously correct way to account for the truth of claims like ‘It is possible that there are Aliens’ without appealing to possible but nonactual objects. In the rest of this article, we will lay out the various attempts to do so in some detail and assess their effectiveness.

---

§1: The Possibilist Challenge to Actualism

The fundamental thesis of actualism is:[1]

> (A) Everything that exists (i.e., everything there is) is actual.

Possibilism is the denial of this thesis and there are various forms of possibilism that correspond to the various ways in which one can deny Thesis (A). (This is explained in more detail in the supplementary document: Three Types of Possibilism.)

The possibilist challenge to actualism is to give an analysis of our ordinary modal beliefs which is consistent with Thesis (A), i.e., which doesn't appeal to possible but nonactual objects. There are two central aspects to the possibilist challenge: the challenge of possible worlds, and the challenge of possible objects. The latter will be the central focus of this article, but, for the sake of completeness, we begin with a brief discussion of the former.

Worlds

Claims such as ‘it is possible that there are Aliens’, ‘it is possible that there is a planet disturbing the orbit of planet X’, and ‘it is necessary that everything is self-identical’ are known as *modal* claims, because the sentential prefixes ‘it is possible that’ and ‘it is necessary that’ indicate a ‘mode’ in which the statements they precede are true. Modal claims are ubiquitous in our thought and discourse. Many of our reflective and creative thoughts seem to be about possibilities (consider, for example, the possibility that there are clean, fuel-efficient automobiles that cause no harm to the environment) and much of our logical

reasoning involves drawing conclusions which, in some sense, necessarily follow from premises that we already believe. Modal logic is the logic of possibility and necessity and the study of modal logic, as a discipline, has flourished in the latter half of the twentieth century. This was due in no small part to the introduction of the concept of *possible worlds* to investigate the truth conditions of modal claims. A large part of the logic of possibility and necessity seems to be captured by treating the modal operators ‘it is necessary that’ and ‘it is possible that’ as quantifiers over possible worlds. That is, the following semantic analyses seem to capture a large part of the logic of modality:

> (a) The statement ‘It is necessary that *p*’ (‘$\Box p$’) is true just in case *p* is true in all possible worlds.
>
> (b) The statement ‘It is possible that *p*’ (‘$\Diamond p$’) is true just in case *p* is true in some possible world.

Notice that it is a consequence of analysis (b) that true claims asserting a possibility imply the existence of possible worlds.

On the face of it, then, the possible worlds analysis of basic modal statements just sketched appears to entail the existence of nonactual possible worlds, and hence appears directly to contradict Thesis (A). Consequently, actualists either have to try to develop a semantics for modal statements in terms that do not entail the existence of nonactual possible worlds, or at least to provide an account of possible worlds on which this consequence is rendered metaphysically innocuous.

The power of the possible worlds semantics -- and the distinct lack of any persuasive alternatives -- is very attractive to many actualists, and they are loathe to give it up (so long, of course, as they do not have to abandon actualism). Consequently, actualists typically grasp the second horn of the above dilemma and adopt some sort of actualistically acceptable, "sanitized" version of this theory on which possible worlds are conceived as theoretical *abstract* objects which actually exist. Many such theories of abstractly-conceived worlds have been developed, some with better success than others (see, for example, Plantinga [1974] and [1976], Chisholm [1976], Fine [1977], Adams, [1974], van Inwagen [1986], or Zalta [1983] and [1993]). Some take worlds to be maximal possible states of affairs, others take them to be maximal possible properties or propositions, still others treat them as maximal consistent sets of some sort, and yet others treat them as part of a more general theory of abstract objects. For purposes here, it will serve well enough just to assume some generic version of this view on which such abstractly conceived worlds can perform their theoretical tasks in virtue of certain actualistically unobjectionable modal properties. A detailed version of such an account, and some of its philosophical ramifications, can be found in the supplementary document on An Account of Abstract Possible Worlds.

Mere *Possibilia*

The second step in the actualist analysis of modality is to find a way to do without possible but nonactual individuals or, at least, a way to replace them with less objectionable entities like properties of some ilk.

Possible but nonactual individuals -- also known as *mere possibilia* or *contingently nonactual* individuals -- seem to be required for the analysis of modal claims involving quantifiers such as ‘there is’ or ‘there exists’. Consider, first, a non-modal quantifier claim, such as ‘There are Aliens’. Such a claim might be regimented in first-order logic as "There exists an *x* such that *x* is an Alien", or in formal terms (in which ‘*Ax*’ abbreviates the predicate ‘*x* is an Alien’): $\exists xAx$.

Now consider the modal claim ‘There could have been Aliens’. It is natural to regiment this claim as "It is possible that there exists an *x* such that *x* is an Alien", which is typically formalized as follows:

(1) $\Diamond\exists xAx$.

Now, if we deploy some acceptable theory of possible worlds, we know that sentence (1) is true if and only if:

(2) There exists a possible world **w** and there exists an individual *x* such that *x* is an Alien at **w**.

But, it is a fact about the logic of the quantifier ‘there exists’ that such quantifiers ‘commute’ with one another. In other words, (2) implies (3):

(3) There exists an individual *x* and there exists a possible world **w** such that *x* is an Alien at **w**.

So the truth conditions of (1) imply (3). But if (3) is true, then so is the ordinary modal claim ‘Something is possibly an Alien’, i.e.,

(4) $\exists x\Diamond Ax$

for which (3) provides the truth conditions. Thus, given the simplest logic concerning modal and quantifier claims, (1) implies (4). In other words, the simplest quantified modal logic tells us that (5) implies (6):

(5) It is possible that there exists an *x* such that *x* is an Alien.

(6) There exists an *x* such that it is possible that *x* is an Alien.

The problem for the second step of the actualist treatment of modality may now be stated more precisely, namely, Thesis (A) is inconsistent with (6). Thesis (A) asserts that everything actually exists. But (6) seems to assert the existence of a possible Alien. There seem to be no candidates among the actually existing individuals which we might plausibly identify as a possible Alien.[2] Thus, the consequences of our ordinary modal beliefs that are valid according to the simplest quantified modal logic seems to be

inconsistent with actualism.[3]

Since it seems reasonable to want to hang on to such ordinary modal beliefs as (5), there is an apparent incompatibility between the simplest quantified modal logic and actualism. This is only the tip of the iceberg, however, for the problem described in the previous paragraph resurfaces each time we ‘nest’ or ‘iterate’ modalities. Consider, for example, the following sentences:

(7) The Pope (i.e., Karol Wojtyla) could have had a son who could have become a priest.

(8) There could be a planet disturbing the orbit of Pluto and it could have a period of *n* years.

Such sentences seems to be representable as follows:

(9) $\Diamond\exists x(Sxp \;\&\; \Diamond Px)$

(10) $\Diamond\exists x(Lx \;\&\; Dxp \;\&\; \Diamond Pxn)$

These cases pose a serious problem for any actualist metaphysics. Even if we assume that actualists can successfully develop a metaphysics and logic that explain the truth of the first occurrence of ‘could’ in (7) and (8), respectively, a serious question arises concerning the second occurrence. The simplest logic of the second occurrence of the "nested" modal operator in (9) and (10) would suggest that it describes a modal fact about a possible individual -- a possible son of the pope in (9), and a possible planet disturbing the orbit of Pluto in (10). (9) seems to assert that a possible son of the pope has the modal property of *possibly becoming a priest*. (10) seems to assert that the possible planet disturbing Pluto has the modal property *possibly having a period of n years* (for some *n*). These cases of ‘nested’ modalities and the problems they pose for actualism were first discussed in a forceful way in McMichael [1983]. We will return to this issue at several points below.

Where We Go From Here

As the reader who works through the remainder of this essay will discover, the simplest quantified modal logic has numerous consequences that seem incompatible in some way or another with actualism. In the next section, we will discover still other such consequences. Though we have succeeded in describing the issues surrounding actualism in more precise terms, we have only scratched the surface of the debate. Much of the debate turns on the precise characteristics of the modal logic being proposed as a logic for actualism. This debate can only be understood if one can contrast the characteristics of these proposed alternative logics with the characteristics of the simplest modal logic. Thus, we will spend the next section of this essay describing the characteristics of the simplest modal logic. Only then will we be in a position to evaluate the more complicated alternatives developed by actualists in the attempt to avoid commitment to nonactual possibles. For example, it is important to see just how Kripke's modal logic (Kripke [1963]) employs a variety of special techniques that yield a logic consistent with Thesis (A) (these will be documented below).

The remaining sections of this essay, therefore, contain the following material. In Section §2, we describe, in a precise way, both the characteristics of the simplest quantified modal logic and its controversial theorems. (As we acquire more sophisticated logical tools, we will revisit some of the examples already discussed; the redescription of these examples in more sophisticated logical terms may prove to be instructive.) We also show why each of the controversial theorems is objectionable from the standpoint of actualism. In Section §3, we outline a modal system developed by Saul Kripke that appears to be consistent with Thesis (A). However, in Section §4, we'll discover that Kripke's system introduces special problems of its own. Finally, in Section §5, we discuss the various attempts actualists have made to work within a Kripke-style framework to solve these problems and to find a metaphysical theory of necessity and possibility which is consistent with Thesis (A). However, we will also examine the attempts of some actualists who have recently discovered a new interpretation of the simplest quantified modal logic which is consistent with Thesis (A).

§2: The Simplest Quantified Modal Logic

A first-order quantified modal logic is a group of logical axioms and rules of inference that systematizes the logically true sentences of a standard first-order modal language with identity (**L**) relative to some class of interpretations of this language. The language **L** is defined just like the language of the predicate calculus with identity, but with the following additional clause in the definition of a 'formula': whenever φ is a formula, so is $\Box\varphi$. Thus, the language will have constants and variables for individuals, *n*-place predicates, atomic formulas such as '$P^n a_1 ... a_n$' and '$x=y$', and the usual molecular, quantified and modal formulas involving the logical notions expressed by '$\neg$' (the negation symbol), '$\rightarrow$' (the symbol for forming conditionals), '$\forall$' (the universal quantifier), and '$\Box$' (the modal operator). The other logical connectives, such as '&' (and), '$\vee$' (or), and '$\equiv$' (iff), and the 'existential' quantifier '$\exists$', are all defined in the usual way. The formula $\Diamond\varphi$ is defined as $\neg\Box\neg\varphi$. (To assert that φ is possibly true is to say that φ is not necessarily false.) From this definition, the equivalence of $\Box\varphi$ and $\neg\Diamond\neg\varphi$ also follows. For convenience, a complete specification is provided in the supplementary document A First-order, Quantified Modal Language. It would serve well to spend a moment or two examining these definitions to making sure that you understand the kinds of statements that are expressible in this language.

The simplest semantics for the language **L** defines a class of interpretations having two distinguishing features: (1) each interpretation **I** in the class has just two, mutually exclusive domains--a nonempty domain of possible worlds (which includes a distinguished "actual world" $\mathbf{w_0}$) and a nonempty domain of individuals, and (2) given any individuals $\mathbf{i}_1$,..., $\mathbf{i}_n$ in the domain and given any possible world **w**, each interpretation **I** specifies, for each *n*-place predicate '*R*', whether '*R*' applies to $\mathbf{i}_1$,..., $\mathbf{i}_n$ at **w** or not. Given that specification, the semantics then defines truth conditions for every formula of the language. The definition of truth even accomodates 'open formulas' (i.e., formulas with free variables) by appealing to assignment functions **f** which assign to each variable *x* some member **f**(*x*) of the domain of individuals. Moreover, given any interpretation **I** and assignment function **f** to the variables, a denotation function **d** relative **I** and **f** is defined for the terms (constants and variables) of the language. When τ is a constant,

$\mathbf{d}_{\mathbf{I},\mathbf{f}}(\tau)$ is the individual in the domain that **I** assigns to τ. When τ is a variable, $\mathbf{d}_{\mathbf{I},\mathbf{f}}(\tau)$ is $\mathbf{f}(\tau)$.

The semantic notion 'φ is true (under interpretation **I** and assignment **f**) at world **w**' ('true$_{\mathbf{I},\mathbf{f}}$ at **w**') is then defined recursively for all of the formulas of the language. The three mosts important parts of this definition for quantified modal logic are the clauses for atomic, quantified, and modal formulas. Here are examples of each:

1. The open, atomic formula '*Px*' is true$_{\mathbf{I},\mathbf{f}}$ at **w** just in case **I** specifies that '*P*' applies to $\mathbf{d}_{\mathbf{I},\mathbf{f}}(x)$ at **w**.
2. The quantified formula '$\forall xPx$' is true$_{\mathbf{I},\mathbf{f}}$ at **w** just in case, for all individuals **a**, '*Px*' is true$_{\mathbf{I},\mathbf{f}[x,\mathbf{a}]}$ at **w**, where $\mathbf{f}[x,\mathbf{a}]$ is **f** if $\mathbf{f}(x) = \mathbf{a}$, and otherwise is just like **f** except that it assigns **a** to *x* instead of $\mathbf{f}(x)$. (A little less formally, '$\forall xPx$' is true$_{\mathbf{I},\mathbf{f}}$ at **w** just in case, for all individuals **a**, the predicate '*P*' applies to **a** at **w**.)
3. The open, modal formula '$\Box Px$' is true$_{\mathbf{I},\mathbf{f}}$ at **w** just in case for every possible world $\mathbf{w}'$, '*Px*' is true$_{\mathbf{I},\mathbf{f}}$ at $\mathbf{w}'$.

A formula φ (which may have the variable *x* free) is then defined to be true$_{\mathbf{I}}$ just in case for every assignment **f**, φ is true$_{\mathbf{I},\mathbf{f}}$ at the actual world $\mathbf{w}_0$. (Note that when φ is a closed formula (i.e., a sentence), then if φ is true relative to some assignment to the variables, it is true relative to all assignments to the variables.) A formula is logically true just in case it is true$_{\mathbf{I}}$ in all interpretations **I** (in this class of interpretations). For convenience, we reproduce here a precise definition in the supplementary document The Simplest Semantics for a Quantified Modal Language. It would serve well to study these definitions if they are unfamiliar. (Readers with some familiarity with modal logic will recognize that we have formulated the semantics without an accessibility relation. However, no such relation is required for a correct semantics of S5, which, in order to keep things simple, we will be presupposing henceforth.)

The simplest quantified modal logic (SQML) systematizes the logically true sentences of **L** relative to the simplest semantics. SQML combines the logical axioms and rules of inference from classical propositional logic, classical first-order quantification theory, the logic of identity, and S5 modal logic. We presuppose here that the laws of classical first-order logic with identity are known. The system S5 (aka KT5) adds three axioms to classical first-order logic with identity--the K axiom, the T axiom, and the 5 axiom (see below)--and adds the Rule of Necessitation (RN) (which states that whenever φ is a theorem, so is $\Box\varphi$). Each of the logical axioms of the resulting SQML is true in every interpretation in the class described in the previous paragraph. Moreover, the rules of inference 'preserve truth' (and preserve logical truth). That is, the rules of inference permit one to infer only (logical) truths from any set of premises consisting solely of (logical) truths. Notice that open formulas are assertible as axioms and provable as theorems in SQML. For convenience, we reproduce these in the supplementary document The Simplest Quantified Modal Logic. Familiarity with this logic will be presupposed in what follows.

The problem that SQML poses for actualist philosophers is that whereas all of the logical axioms appear to be true, some of the logical consequences of these axioms appear to be false. Consider first the fact that the new modal axioms added by SQML to classical first-order logic, i.e., the K, T, and 5 axioms, all seem

true. The K axiom asserts that if a conditional is necessary, then if the antecedent is necessary, so is the consequent:

K axiom: $\Box(\varphi \rightarrow \psi) \rightarrow (\Box\varphi \rightarrow \Box\psi)$

It is easy to see that this is true in every interpretation of the class of simplest interpretations: if a conditional is true in every possible world and the antecedent of the conditional is true in every world, then the consequent of the conditional is true in every world.

The ‘T’ axiom asserts that a formula true in every possible world is simply true:

T axiom: $\Box\varphi \rightarrow \varphi$

Clearly, this is true in all interpretations--if a sentence is true in every possible world, it is true in the distinguished actual world.

The ‘5’ axiom asserts that if a formula φ is possible, then it is necessarily the case that it is possible:

5 axiom: $\Diamond\varphi \rightarrow \Box\Diamond\varphi$

It is not hard to see that this is logically true. If a formula is true in some possible world, then from the point of view of every possible world, the formula is true in some possible world. That is, if a formula is true at some possible world, then at every possible world, there is some possible world where the formula is true. (The formal validity of the 5 Axiom is proved in the supplementary document The 5 Axiom is Logically True.)

Controversial Consequences of SQML

However, the controversies surrounding actualism and modal logic center on the following theorems, (the instances of) which are all logically true and provable from the axioms and rules of SQML:

BF: $\forall x\Box\varphi \rightarrow \Box\forall x\varphi$

NE: $\forall x\Box\exists y\, y{=}x$

CBF: $\Box\forall x\varphi \rightarrow \forall x\Box\varphi$

BF, NE, and CBF are, respectively, the Barcan Formula, Necessary Existence, and the Converse Barcan Formula. It is reasonably straightforward to establish that NE and the instances of BF and CBF are all logically true and that they are all derivable from the axioms and rules of SQML. The proofs of these claims are provided in following supplementary documents:

[The Barcan Formula is Logically True](#)
[The 'Necessary Existence' Principle is Logically True](#)
[The Converse Barcan Formula is Logically True](#)

We also show how to use the axioms and rules of SQML in the following documents:

[Proof of the Barcan Formula in S5](#)
[Proof of 'Necessary Existence' in S5](#)
[Proof of Converse Barcan Formula in S5](#)

Before we turn to the discussion of why actualists find BF, NE, and CBF objectionable, there are two minor details to attend to. The first is that the Barcan Formula is often discussed in the following equivalent form (indeed, this was the formulation that played a role in our discussion in the first section of the present essay):

$$\Diamond\exists x\varphi \rightarrow \exists x\Diamond\varphi$$

(In the supplementary document, [Proof of Barcan Formula Equivalent](#), we show that this statement is equivalent to BF.) Referring back to our Alien example, then, BF in this form, where φ is '*Ax*', asserts that proposition (1) of the previous section implies (4), or, in terms of their ordinary language counterparts, that (5) implies (6).

Why Actualists Find These Consequences Unacceptable

With the machinery of SQML laid out before us, it is instructive to consider why its consequences BF, NE, and CBF offend the actualist. Recall that, according to actualism, everything there is, in any sense, is actual. Consider first the Barcan Formula. We have seen how BF leads to problems in the case of the Alien example, but, to drive the point home, it is perhaps worth considering yet another case that has appeared in the literature. Linsky and Zalta (1994) clearly express the problem for actualists by having the reader consider a sisterless person *b*; presumably, though sisterless in fact, most everyone would agree that it is at least possible that *b* have a sister. But given that possibility,

> ... BF requires that *there exists* something that is possibly *b*'s sister. Since *b* has no sisters, which existing object is it that is possibly *b*'s sister? Some actualists, notably Ruth Marcus [1986], might defend BF by pointing to an existing woman (possibly one closely related to *b*) and suggesting that she is the thing which both exists and which is possibly *b*'s sister. But the great majority of actualists don't accept this idea, for they subscribe to certain essentialist views about the nature of objects. For example, they believe that women who aren't *b*'s sister could not have been (in a metaphysical sense) *b*'s sister. This is a fact about their very nature, one concerning their origins. ... Since there seems to be no *actually existing* thing which is possibly *b*'s sister, they conclude BF is false. We think the

> essentialist intuitions leading to this conclusion are not unreasonable, and so understand why these actualists take BF to be false. Indeed, it seems that BF, in general, is incompatible with the intuition that there might have been something distinct from every actual thing. It is hard to see how that intuition could be compatible with a principle which seems to require that every possibility be grounded in something that exists. This is further evidence actualists have against the acceptability of BF. But since they still want to make sense of modal discourse in terms of possible world semantics, they reject the Barcan formula as having unacceptable consequences, and search for a modal semantics on which it is not valid.

Consider next NE. For actualists, this explicitly says that for any object *x*, necessarily something exists that is identical with *x*. Now most actualists accept the following definition of what it is for an object to exist:

$$x \textit{ exists} =_{df} \exists y(y = x)$$

Given this definition, NE says that everything necessarily exists. (hence our abbreviation ‘NE’). Prior in [1957] was especially concerned by this, pointing out that classical quantified modal logic was "haunted by the myth that whatever exists exists necessarily." Note that NE applies even to those objects not named by a constant of the language. These consequences run counter to our ordinary (modal) intuitions. They are not inconsistent with Thesis (A), but are instead inconsistent with the reasonable belief that some objects might not have existed. Actualists see this as an additional and independent reason to abandon SQML.

Another problem with NE is that it leads to an even stronger result. By applying the Rule of Generalization and then the Rule of Necessitation to NE, one obtains:

NNE: $\Box\forall x\Box\exists y\, y=x$

This asserts that it is necessary that everything necessarily exists. It follows that it is not even possible for there to be contingent individuals. To see why, note that an actualist would define ‘contingent individual’ as follows:

$$x \textit{ is contingent} =_{df} \Diamond\neg\exists y(y = x)$$

Consequently, the claim that there are contingent individuals would be formulated as:

$$\exists x\Diamond\neg\exists y(y = x)$$

But it now follows from NNE that it is not possible that there are contingent individuals:

$\neg\Diamond\exists x\Diamond\neg\exists y(y = x)$

(The proof is left as an exercise.) If this is a consequence of SQML, it is no wonder actualists are dissatisfied.

Finally, there is CBF. For the actualist, the main problem with CBF is that in SQML it implies NE in conjunction with the thesis known as *Serious Actualism*. Serious Actualism is the thesis that it is not possible for an object to have a property without existing, i.e., that if an object exemplifies a property at a world, it exists at that world. [See Plantinga [1983], [1985], Menzel [1991], Pollock [1985], and Deutsch [1993] for various discussions of Serious Actualism.] In semantic terms, this amounts to the constraint that an object in the extension of a property at a world must fall under the range of the quantifier at that world. Serious Actualism is often expressed by the following schema of the object language:

SA: $\Box[\varphi \rightarrow \exists y\, y{=}x]$, where φ is atomic and contains x.

Note that SA is a theorem of SQML (the proof is a simple exercise) and seems consistent with the actualist point of view. But from SA and CBF, one can rederive NE from any (logically) necessary property in the system. (See A Derivation of NE from SA and CBF.) Thus, even if there were a way to block the direct derivation of NE, the alternative derivation of NE from CBF and SA shows that serious actualists could not accept SQML unless CBF is somehow invalidated.

As noted, Arthur Prior was the first to realize the controversial consequences of SQML. Prior himself was a staunch actualist, and dealt with the problem by developing an alternative quantified modal logic that differs significantly from SQML, and which does not have the controversial principles above as theorems. A more detailed account of Prior's approach can be found in the supplementary document Prior's Modal Logic.

§3: Kripke's System

Given the above consequences of SQML, one can understand why actualists would seek a reformulation of quantified modal logic that both: (1) defines interpretations so that BF, NE, and CBF are not logically true, and (2) weakens the proof theory of SQML so that BF, NE, and CBF are not derivable as theorems of the logic. Kripke's logic appealed to actualists and serious actualists for these very reasons. The system of Kripke [1963] invalidates BF, NE, and CBF both model-theoretically and proof-theoretically.

It is illuminating both to see exactly how Kripke was able to construct interpretations on which BF, NE, and CBF are not logically true and to see exactly how Kripke modified the logic of SQML so that these these schemata and sentences are no longer theorems. These techniques will be the subject of the next two subsections.

Kripke Models

The key insight in Kripke's quantified modal logic is the replacement of the single domain **D** of individuals in the interpretation of a first-order modal language with a function **dom** that assigns to each world **w** its own distinct domain of individuals **dom**(**w**). No restrictions are placed on the domain of a world; any set of individuals, including the empty set, will do. Thus, instead of a single domain common to all worlds, domains are permitted to vary from world to world. Intuitively, of course, **dom**(**w**) represents the objects that *exist* in **w**. In particular, the domain of the actual world represents--of course--the things that are actual, the things that exist simpliciter. Interpretations like this for first-order modal languages in which each world has its own domain are known as *Kripke models*.

The central semantic difference between Kripke models and interpretations for SQML is that, in a Kripke model, when a quantified formula $\forall x\varphi$ is evaluated at a world **w**, the quantifier ranges only over the objects that exist in the domain of **w**. Thus, in particular, the sample clause in the definition of truth for quantification above must be revised for Kripke models **M** as follows, where, again, **f** is an assignment function:

> The quantified formula '$\forall xPx$' is true$_{\mathbf{M},\mathbf{f}}$ at **w** just in case, for all individuals *a* in **dom**(**w**), 'Px' is true$_{\mathbf{M},\mathbf{f}[x,\mathbf{a}]}$ at **w**, where **f**[x,**a**] is **f** if **f**(x) = **a**, and otherwise is just like **f** except that it assigns **a** to x instead of **f**(x).

Again, a little less formally, '$\forall xPx$' is true$_{\mathbf{I},\mathbf{f}}$ at **w** just in case, for all individuals **a** *that exist in **w***, the predicate 'P' applies to **a** at **w**.

Kripke's changes to the model theory of first-order modal languages are relatively simple. Nonetheless, unlike the model theory for SQML, Kripke's model theory yields a set of logical truths that is fully compatible with actualism. In particular, all three of the principles with which the actualist takes issue -- BF, NE, and CBF -- turn out to be invalid in Kripke's semantics. Consider first BF in the form

> $\Diamond\exists x\varphi \rightarrow \exists x\Diamond\varphi$

For definiteness, let φ be the formula 'Ax' expressing that x is an Alien (in the sense of 'Alien' introduced above). As we noted, even though there are no Aliens in the actual world $\mathbf{w_0}$, there could have been; that is, there is a possible world **w** in which there are Aliens. Thus, on Kripke's way of evaluating quantified formulas, the antecedent to BF -- '$\Diamond\exists xAx$' -- comes out true at the actual world: '$\Diamond\exists xAx$' is true at $\mathbf{w_0}$ if and only if there is some world **u** at which '$\exists x$Ax' is true, and that, in turn, is true at such a **u** just in case some entity *that exists in **u*** is an Alien there. Assuming, as we are, that there is such a world, then, '$\Diamond\exists x$Ax' is indeed true, i.e., true at the actual world. However, as we also noted, no actually existing thing is an Alien. Thus, there is nothing in the domain of the actual world such that '$\Diamond Ax$' is true of it, that is, nothing **a** in the actual world and no world **u** are such that 'A' is true of **a** at **u**. So, in the case in question, the antecedent of BF is true, but the consequent is false. So BF is not valid, that is, there are models in which some of its instances are false.

It should be obvious why NE is also invalid in Kripke's semantics: domains of worlds can be empty. Thus, let $\mathbf{M_1}$ be a Kripke model containing at least one actual individual (i.e., at least one object **a** $\in$ **dom**($\mathbf{w_0}$)) and a world **w** that has an empty domain. Then, obviously, **a** does not exist in **w**, and hence '$\exists y\, y=x$' is false at **w** when '**a**' is assigned to *x*. Thus, '$\Box\exists y\, y=x$' is false at $\mathbf{w_0}$ when **a** is assigned to '*x*', and so, because **a** is in the domain of the actual world $\mathbf{w_0}$, NE (hence also NNE, of course) is false in $\mathbf{M_1}$.

Finally, we note that CBF is invalid in Kripke's semantics. First, let $\mathbf{M_2}$ be a Kripke model in which NE is false. (We just proved the existence of such a model in the previous paragraph, of course.) Next, let the predicate '*P*' express a property in $\mathbf{M_2}$ that is *universal* and *existence-entailing*, that is, a property which is exemplified at each world **w** by everything that exists at **w**. (Such a property is said to be existence-entailing because, necessarily, anything that has it exists. The property *existence*, of course, is the simplest example of such a property.) We can represent the universal, existence-entailing character of this property in the predicate '*P*' formally in $\mathbf{M_2}$ simply by stipulating that the extension of '*P*' at any world **w** of $\mathbf{M_2}$ is **dom**(**w**), so that all and only the things that exist at each world are in the extension of *P* at that world. Now, note that, under these conditions, it is true in $\mathbf{M_2}$ (i.e., true at the actual world $\mathbf{w_0}$ of $\mathbf{M_2}$) that $\Box\forall xPx$: intuitively, everything that exists in every possible world has the property *P* in that world. Let **a** be any object in the actual world $\mathbf{w_0}$ that fails to exist in some world **w**. (Since, by hypothesis, NE fails in $\mathbf{M_2}$, there must be such an object in **dom**($\mathbf{w_0}$).) Because *P* is existence-entailing, **a** is not in the extension of '*P*' at **w**. So there is something in the actual world $\mathbf{w_0}$ that does not have the property *P* in every possible world, i.e., '$\forall x\Box Px$' is false in $\mathbf{M_2}$. Hence, the instance '$\Box\forall xPx \rightarrow \forall x\Box Px$' of CBF is false in $\mathbf{M_2}$.

Note that the invalidity of CBF opens the door back up to serious actualism (SA) in Kripke's semantics, as it was the combination of SA with CBF that led to trouble (i.e., trouble for the actualist) in SQML. And it is easy to see formally that this is the case by constructing a Kripke model in which SA is true. Note first that the thesis of serious actualism can be expressed as the thesis that all properties are existence-entailing; there is no possible world in which something has a property but fails to exist in that world. In first-order languages, properties are represented by predicates, and having a property is represented semantically by being in the extension of a predicate. Thus, to represent a property as existence-entailing in a Kripke model, one simply ensures that, at every possible world **w**, the extension of the predicate representing that property consist only of things that exist in **w**. Hence, to represent *all* properties as existence entailing, and hence, to make SA true, one ensures that this is so for all the predicates of one's language. Formally, then, let $\mathbf{M_3}$ be any Kripke model satisfying the condition that, for every *n*-place predicate *F* and world **w**, *F* is interpreted so that, at **w**, *F* applies only to things that exist in **w**; more formally, for individuals $\mathbf{i}_1, \ldots, \mathbf{i}_n$ of $\mathbf{M_3}$, *F* applies to $\mathbf{i}_1, \ldots, \mathbf{i}_n$ at **w** only if $\mathbf{i}_1, \ldots, \mathbf{i}_n \in$ **dom**(**w**). This condition ensures that SA is true in $\mathbf{M_3}$.

The compatibility of SA with Kripke's semantics is yet further evidence of its suitability as a formal semantics for the actualist. A question that remains is: What sort of *logic* does this semantics yield?

Kripke's Quantified Modal Logic

A logic formulated in a given language **L*** is said to be *sound* and *complete* with respect to a semantics for **L*** if and only if all and only those formulas of **L*** that are valid relative to that semantics (i.e., true in every interpretation or model of the semantics) are theorems of the logic. A sound and complete logic for a semantics is a good thing, of course, as it provides a purely syntactic, proof-theoretic mechanism for demonstrating the semantic validity of formulas and arguments in the language.[4].

SQML is sound and complete relative to the semantics given for its language **L** above. Since BF, NE, and CBF are invalid in Kripke's semantics, SQML is obviously not sound and complete for it; more specifically, it is not sound: some of SQML's theorems--notably, BF, NE, and CBF--are not valid, as we saw in the previous section. Hence, Kripke must modify SQML to block their derivation without blocking the derivation of any valid formulas.

The key element to Kripke's solution to this problem is the generality interpretation of free variables. The proof of NE in SQML relies crucially on the ability to derive theorems involving free variables, and more specifically on the application of the rule of Necessitation to such theorems. As described in the supplementary document Proof of ‘Necessary Existence’ in S5, the proof makes use of the following instances of logical axioms:

- $x=x$
- $\forall y\, y \neq x \rightarrow x \neq x$.

By contraposition and quantifier exchange rules, the latter axiom is equivalent to $x=x \rightarrow \exists y\, y=x$. Thus, given $x=x$, we have $\exists y\, y=x$. The crucial step now is the application of Necessitation to this formula -- containing, we note, the free variable x -- to yield $\Box\exists y\, y=x$, which in turn yields NE, by Generalization.

To repair this "flaw" in SQML, Kripke proposes no changes to SQML other than this: a formula φ containing free variables $x_1,..., x_n$, when asserted as a theorem (and hence, in particular, as an axiom), is taken to be an abbreviation for its universal closure $\forall x_1...\forall x_n\varphi$. Thus, under this proposal, the axioms used in the proof of NE noted above are no longer assertible as theorems (they cannot appear in the lines of a proof) --- they must be taken to be abbreviations of:

- $\forall x\, x=x$
- $\forall x[\forall y\, y \neq x \rightarrow x \neq x]$

respectively. From the second axiom displayed above we can derive $\forall x(x=x \rightarrow \exists y\, y=x)$ and, from this $\forall x\, x=x \rightarrow \forall x\exists y\, y=x$ (by the quantifier distribution axiom). So using the first axiom displayed above, we can now derive $\forall x\exists y\, y=x$ by Modus Ponens, and, finally, by Necessitation we can derive only $\Box\forall x\exists y\, y=x$. This latter, for Kripke, is uproblematically and uncontroversially true -- in every possible world, every individual existing in that world is identical to something (viz., itself). To derive NE from

this, however, we need CBF -- in particular, the instance $\Box\forall x\exists y\, y=x \rightarrow \forall x\Box\exists y\, y=x$. But, as Kripke points out, the proof of CBF in SQML also depends essentially on an application of Necessitation to a theorem containing a free variable -- the same "flaw" that infects the proof of NE. (See the inference from line 1 to line 2 in the supplementary document Proof of the Converse Barcan Formula in S5.) Hence, it, too, fails under the generality interpretation of free variables. The proof of BF fails for the same reason. Hence, the SQML proofs of all three actualistically unacceptable principles fail in Kripke's system.

The failure of those particular proofs, of course, does not mean that the principles in question cannot be proved some other way. However, Kripke guarantees their unprovability in his system by showing that the system is sound and complete relative to his semantics. Soundness, in particular, tells us that no invalid formula is provable in the system. Hence, since NE, CBF, and BF are all invalid in Kripke's semantics, soundness guarantees that they are all unprovable in his system.

§4: Is Kripke's System Actualist?

On the face of it, Kripke's system provides the actualist with a powerful alternative to SQML. However, although BF, NE, and CBF are neither valid nor provable in Kripke's system, the system is open to several serious objections.

First, Kripke regards the loss of free variables from assertible sentences as a mere inconvenience. However, much of mathematical reasoning is carried out in terms of sentences with free variables, and one should at least wonder why modal logic, as opposed to classical logic, can't be formulated with free variables in assertible sentences. Far more serious, however, is the fact is that, as the system stands, one cannot add constants for contingent beings. For suppose we add a constant '*c*' to Kripke's system. As noted in the last section, $\forall x\, x=x \rightarrow \forall x\exists y\, y=x$ is a theorem of Kripke's logic. Hence, by the identity axiom $\forall x\, x=x$ we have $\forall x\exists y\, y=x$, and so by universal instantiation it follows that $\exists y\, y=c$. However, by necessitation it follows that $\Box\exists y\, y=c$, i.e., that *c*, whatever it may be, is a necessary being. Thus, in Kripke's system as it stands, one cannot consistently assert, e.g., that Socrates is a contingent being, $\neg\Box\exists y\, y=s$, surely a seriously undesirable feature in a logic that is intended properly to capture our modal intuitions.

Alarming as this problem might be, it is more a formal rather than a philosophical objection to Kripke's system. Though Kripke himself might not be particularly pleased at the prospect, it seems that the proper response to these problems is simply to alter those features of classical quantification theory and/or classical propositional modal logic that give rise to invalid inferences such as the above. (Arguably, Kripke has already made a similar move in adopting the generality interpretation of free variables.) Obvious suspects here are universal instantiation and necessitation. After all, there is nothing sacrosanct about either classical quantification theory or classical modal logic. If they are inconsistent with strong modal intuitions, then their revision is required and fully warranted.

So its current inability to name contingent beings does not of itself constitute much of an objection to

Kripke's system. It is likely that it could be patched up so as to allow it this expressive capacity. Far more serious is the fact that, despite the invalidity and unprovability of the actualistically objectionable principles BF, NE, and CBF, Kripke's system does not appear to have escaped ontological commitment to possibilia. A model theory provides a *semantics* for a language -- an account of how the truth value of a given sentence of the language is determined in a model by the meanings of its semantically significant component parts, notably, the meanings of its names, predicates, and quantifiers. Now, truth-in-a-model is not the same as truth simpliciter. However, truth simpliciter is usually understood simply to be truth in an *intended* model, a model consisting of the very things that the language is intuitively understood to be "about". So if we are to take Kripke models seriously as an account of truth for modal languages, then we must identify the intended models of those languages. And for this there seems little option but to take Kripke's talk of possible worlds literally: the set W in an intended Kripke model is the set of all possible worlds. If so, however, it appears that Kripke is committed to possibilia. For suppose the modal operators are literally quantifiers over possible worlds. And suppose it is possible that there be objects -- Aliens, for example -- that are distinct from all actually existing objects. Letting '*A*' express the property of being an Alien, we can represent this proposition by means of the sentence '$\Diamond\exists yAy$ & $\neg\exists x\Diamond Ax$', i.e., while there could be Aliens ($\Diamond\exists yAy$), no actually existing thing could be an Alien ($\neg\exists x\Diamond Ax$). On Kripke's semantics, the first conjunct of this sentence can be true only if there is a possible world *w* and an object *a* such that *a* is an Alien at *w*. But given the second conjunct, any such object *a* is distinct from all actually existing things. Hence, using Kripke's semantics to provide us with an account of truth, we find ourselves quantifying directly over possible worlds and mere *possibilia*. That BF, NE, and CBF are unprovable in Kripke's system, it seems, is metaphysically irrelevant. For it appears that, nonetheless, the semantics itself is wholly committed to possibilism.

An option for the actualist here, perhaps, is simply to deny that Kripke models have any genuine metaphysical bite. The real prize is the logic, which describes the modal facts of the matter *directly*. The model theory is simply a formal *instrument* that enables us to prove that the logic possesses certain desirable metatheoretic features, notably consistency. But this position is unsatisfying at best. Consider ordinary "Tarskian" model theory for nonmodal first-order logic. Intuitively, this model theory is more than just a formal artifact. Rather, when one constructs an intended model for a given language, it shows clearly how the semantic values of the relevant parts of a sentence of first-order logic -- the objects, properties, relations, etc. in the world those parts signify -- contribute to the actual truth value of the sentence. The semantics provides insight into the "word-world" connection that explains how it is that sentences can express truth and falsity, how they can carry good and bad information. The embarrassing question for the actualist who would adopt the proposed instrumentalist view of Kripke semantics is: what distinguishes Kripkean model theory from Tarskian? Why does the latter yield insight into the word-world connection and not the former? Distaste for the metaphysical consequences of Kripke semantics at best provides a motivation for finding an answer to these questions, but it is not itself an answer. The actualist owes us either an explanation of how Kripke's model theory provides a semantics for modal languages that does not commit us to possibilism, or else he owes us a semantical alternative.

§5: Actualist Responses to the Possibilist Challenge

We now turn to the work of actualists who have tried to address the possibilist challenge.

Individual Essences

One of the best known responses to the possibilist challenge was developed by Alvin Plantinga [1974]. The heart of Plantinga's approach is the notion of an *individual essence*. Plantinga's precise definition of this notion is a bit complex, but the idea itself is quite simple. Consider first the venerable distinction between *essential* and *accidental* properties. Intuitively, the essential properties of an object are those properties that make the object "what it is." More exactly, they are the properties that the object couldn't possibly have lacked. Its accidental properties, by contrast, are those that it just happens to have but might well have lacked. Thus, the property **being a horse** is intuitively not a property that the champion racehorse Secretariat could have lacked; he couldn't have been a rabbit, say, or a stone. The property **being a horse** is thus essential to Secretariat. By contrast, Secretariat could easily have lacked the property **being a racehorse**. Under different circumstaces -- if, say, he'd injured a leg as a colt -- he might have spent his days frolicking in the fields. That property is therefore accidental to Secretariat. So the first part of the definition of an individual essence -- the "essence" part -- is that an individual essence is an essential property of anything that has it. And the "individual" part of the definition is simply that if something has a given individual essence, then nothing else could possibly have that same individual essence. (We provide the definition Plantinga actually uses in the document Plantinga's Definition of an Individual Essence.)

Examples of individual essences are a little harder to come by than examples of essential properties. There are fairly strong intuitive grounds for the thesis that having arisen from the exact sperm and egg that one has is an individual essence of every human person, or at least of every human body. A different sperm and the same egg, say, would have resulted in a perhaps similar but numerically distinct person. Less controversial from a purely logical standpoint are what Plantinga calls *haecceities*, i.e., properties like **being Plantinga**, or perhaps, **being identical with Plantinga**, that are "directly about" some particular object. Pretty clearly, Plantinga has the property **being Plantinga** essentially -- he could not exist and lack it; any world in which he exists is, *ex hypothesi*, a world in which he is *Plantinga*, and hence a world in which he exhibits the property in question. Moreover, nothing but the individual Plantinga could have had that property; necessarily, anything that has it is identical to Plantinga. Hence, **being Plantinga** is an individual essence. Importantly, Plantinga takes individual essences, like all properties, to exist necessarily, even if they are not exemplified. (Interested readers may wish to read the supplementary document Background Assumptions for Plantinga's Account.)

Briefly put, Plantinga's solution to the possibilist challenge is to replace the possibilia of Kripke's semantics with individual essences. We follow the development of this solution found in Jager [1982]. Specifically, an interpretation **I** of the first-order modal language **L**, consists again of two mutually disjoint nonempty sets: the set of possible worlds and the set of individual essences. And, as with Kripke, there is a function **dom** that assigns to each possible world **w** its own distinct domain **dom**(**w**). However, instead of the possible individuals that exist in **w**, this domain consists of those individual essences that

are *exemplified* in **w**, or, more exactly, that *would have been exemplified* if **w** had been actual.

But how, exactly, does **I** assign values to predicates? After all, it is not individual essences to which predicates apply at worlds, it is the things that exemplify them; **being an Alien**, if it were exemplified, would not be a property of essences, but of individuals. Plantinga's trick is to talk, not about exemplification, but *coexemplification*. Properties **P** and **Q** are *coexemplified* just in case some individual has both **P** and **Q**. And for any world **w**, **P** and **Q** are *coexemplified in* ***w*** just in case, if **w** were actual, **P** and **Q** would be coexemplified. So, for example, given that there are men who are philosophers, the properties **being a man** and **being a philosopher** are coexemplified in the actual world. Again, any world in which the pope (i.e., Wojtyla) has a child is a world in which the property **being a child of Wojtyla** is coexemplified with an individual essence *E*; any such essence *E*, of course, is unexemplified in the actual world (assuming the lifelong chastity of the pope).

A relation **R** is coexemplified with properties $\mathbf{P}_1,\ldots, \mathbf{P}_n$ (in that order) just in case (i) there are individuals $\mathbf{i}_1,\ldots, \mathbf{i}_n$ that exemplify $\mathbf{P}_1,\ldots, \mathbf{P}_n$, respectively, and (ii) $\mathbf{i}_1,\ldots, \mathbf{i}_n$ stand in the relation **R**. And for any world **w**, **R** is coexemplified with properties $\mathbf{P}_1,\ldots, \mathbf{P}_n$ in **w** just in case, if **w** were actual, **R** would be coexemplified with $\mathbf{P}_1,\ldots, \mathbf{P}_n$. In Plantinga's system, then, a 1-place predicate *P applies to* a given individual essence **e** at a world **w** just in case the property expressed by *P* is coexemplified with the **e** at **w**. And an *n*-place predicate *R* applies to essences $\mathbf{e}_1,\ldots, \mathbf{e}_n$ at **w** just in case the relation expressed by *R* is coexemplified with $\mathbf{e}_1,\ldots, \mathbf{e}_n$ at **w**. For any individual essences $\mathbf{e}_1,\ldots, \mathbf{e}_\mathrm{n}$ and possible world **w** in our interpretation **I**, then, **I** specifies, for each *n*-place predicate *R*, whether or not *R* applies to $\mathbf{e}_1,\ldots, \mathbf{e}_n$ at **w**.

The denotation function **f** for **I** works just as in SQML and Kripke semantics, only now, of course, it assigns essences to variables instead of possibilia. Given this, we can now illustrate the definition of truth for this model theory by means of several instances of its most important clauses:

1. The open, atomic formula '*Px*' is $\text{true}_{\mathbf{I},\mathbf{f}}$ at **w** just in case **I** specifies that '*P*' applies to $\mathbf{d}_{\mathbf{I},\mathbf{f}}(x)$ at **w**.
2. The quantified formula '$\forall xPx$' is $\text{true}_{\mathbf{I},\mathbf{f}}$ at **w** just in case, for all individual essences **e** in **dom**(**w**), '*Px*' is $\text{true}_{\mathbf{I},\mathbf{f}[x,\mathbf{e}]}$ at **w**, where **f**[*x*,**e**] is **f** if **f**(*x*) = **e**, and otherwise is just like **f** except that it assigns **e** to *x* instead of **f**(*x*). (A little less formally, '$\forall xPx$' is $\text{true}_{\mathbf{I},\mathbf{f}}$ at **w** just in case, for all individual essences **e**, the predicate '*P*' applies to **e** at **w**.)
3. The open, modal formula '$\Box\varphi$' ('$\Diamond\varphi$') is $\text{true}_{\mathbf{I},\mathbf{f}}$ at **w** just in case for every (some) possible world **w**, 'φ' is $\text{true}_{\mathbf{I},\mathbf{f}}$ at **w**.

Referring back to our Alien example, then, the proposition that it is possible that there are Aliens, $\Diamond\exists xAx$, is true on this account if and only if there is a possible world **w** and a haecceity **e** such that '*A*' applies to **e** at **w**, i.e., if and only if the property **being an Alien** and **e** are coexemplified in **w**.

Notice that Plantinga's account also has no problem dealing with iterated modalities. The problem, recall, was that sentences like

(9) $\Diamond\exists x(Sxp \& \Diamond Px)$

appear to require mere possibilia to serve as the values of the quantifier, since no actually existing thing could be a son of the current pope. For Plantinga, the solution is simply that quantifiers range over haecceities, and that, in particular, (9) is true in virtue of their being an unexemplified haecceity which, in some possible world is coexemplified with the property **being a son of Wojtyla**, and in another world, that very same haecceity is coexemplified with **being a priest**.

In sum, then, in Plantinga's account there is an individual essence for every *possibile* in Kripke's. And for every property that every *possibile* enjoys at any given world **w** in Kripke's account, there is an individual essence that is coexemplified with that property in (the Plantingian counterpart of) **w**. Plantinga's semantics would thus appear to generate precisely the same truth values for the sentences of a modal language as Kripke's. Hence, it would appear that Plantinga has indeed successfully developed a semantics for modal languages that comports with actualist scruples.

Problems with this Account

Objections to Plantinga's account of actualism are addressed in the document Problems with the Actualist Accounts.

World Stories

Many propositions are *singular* in form. That is, as opposed to general propositions like **All men are animals** and **There are Aliens**, some propositions are, in the words of Arthur Prior, "directly about" specific individuals -- for example, the proposition **Winston Churchill was a German citizen**. Such propositions are typically expressed by means of sentences involving names, pronouns, indexicals, or other devices of direct reference. As we've seen, possibilists believe that there are singular possibilities (i.e., singular propositions that are possibly true) about things that don't actually exist, possibilities involving mere *possibilia*. Similarly, haecceitists also believe that there are singular possibilities that are, in a certain clear sense, directly about things that don't exist, viz., possibilities that, were they actual, would involve the exemplification of haecceities that are in fact actually unexemplified. Say that a *strong* actualist is someone who rejects both nonactual *possiblia* and unexemplified haecceities. For the strong actualist, then, there are no singular propositions directly about things that do not actually exist. Since this is a necessary truth for the strong actualist, it also follows that, had some actually existing individual failed to exist, there have been no singular propositions about that individual. Singular propositions about contingent beings are thus themselves likewise contingent for the strong actualist. A strong actualist, then, as we might put it, believes that all possibilities are either wholly general, or at most are directly about actually existing individuals only.

Several philosophers -- notably, Robert Adams and, building on work of Prior [1977], Kit Fine -- have developed possible world semantics that are strongly actualist. The approach in Adams [1974] centers

around Adams' notion of a possible world, or "world story". For Adams, a world story is a *maximally possible* set of propositions, that is, a set **s** of propositions such that (i) for any proposition **p**, s contains either **p** or its negation ¬**p**, and (ii) it is possible that all the memebers of **s** be true together.[5]. A proposition **p** is *true* in a world story **w**, then, just in case **p** is a member of **w**. Thus, Adams takes a proposition to be possible just in case it is true in some world story. In particular, then, the semantics of our paradigmatic proposition **Possibly, there are Aliens**, i.e., formally,

(1) $\Diamond\exists xAx$,

is straightforward and, on the face of it, innocuous from a strongly actualist perspective: (1) is true if and only if (the proposition expressed by)

(14) '$\exists xAx$' (i.e., the proposition **There are Aliens**) is true at some world.

Problems with this Account

Objections to world stories are addressed in the document Problems with the Actualist Accounts.

World Propositions

Inspired by the work of Arthur Prior, Kit Fine [1977] has developed an approach similar to Adams' which takes account of the contingency of singular propositions. For Adams, a possible world is a certain set of propositions. Fine, by contrast, drawing on an idea of Prior's, identifies a world with a certain type of proposition --- what he calls a *world proposition*. Roughly speaking, a world proposition might be thought of as the infinite conjunction of all of the proposition in one of Adams' world stories. More specifically, a world proposition is a proposition **q** such that it is possible both that **q** be true and that it entail all true propositions. A proposition **p** is then said to be *true in* a possible world, i.e., world proposition, **q** just in case **q** *entails* **p**, i.e., formally, just in case $\Box(\mathbf{q} \rightarrow \mathbf{p})$.

Now, if Fine's account were to parallel Adams', then Fine would now say that, for a proposition to be possible is for it to be true in some possible world, i.e., to be entailed by some world proposition. But Fine is more mindful of the problems that contingent propositions raise for actualism. Consequently, he suggests alternative truth conditions for propositions of the form **Possibly p**, namely, that it is *possible* that **p** be true in some possible world. Thus, for Fine, the full analysis of the iterated modal proposition (9) -- $\Diamond\exists x(Sxp \,\&\, \Diamond Px)$ -- is as follows: (9) is true if and only if

(18) It is possible that '$\exists x(Sxp \,\&\, \Diamond Px)$' (i.e., the proposition **Wojtyla has a son who could have become a priest**) is true at some world **w**.

(18), in turn, is true if and only if

(19) It is possible that, for some some individual *x*, '*Sxp* & ◇*Px*' (i.e., the proposition ***x* is a son of Wojtyla and *x* could have become a priest**) is true at some world **w**,

which, in turn, is true if and only if

(20) It is possible that, for some some individual *x*, '*Sxp*' (i.e., the proposition ***x* is a son of Wojtyla**) is true at some world **w** and, it is possible that, for some world **u**, '*Px*' (i.e., the proposition ***x* is a priest**) is true at **u**.

Thus, all that Fine's account requires in its analyses of (9) is the *possibility* that certain propositions exist -- notably, singular propositions (and, in particular, world propositions) that don't exist in fact but would exist if certain individuals did, as would be the case, e.g., if the pope were to have a son. Unlike Adams account, then, Fine's wears its fully intensional character on its sleeve. It abandons the idea that ordinary modal operators such as "possibly" and "necessarily" can, in general, be analyzed as extensional quantifiers over possible worlds. For some occurrences of those operators -- those in (9), for instance -- are ineliminable.

Problems with this Account

Objections to world propositions are addressed in the document Problems with the Actualist Accounts.

Roles

McMichael [1983a] has proposed an actualist semantics that avoids the objections to haecceities raised against Plantinga and both the loss of compositionality objection and the iterated modalities objection raised against Adams. Like Adams, McMichael rejects haecceities. However, like Plantinga, McMichael introduces a class of actualist surrogates for *possibilia*, which he calls *roles*. McMichael's account builds on a very rich and elaborate theory of relations, and it is necessary to lay out at least some of its basic concepts in order to understand the account.

For McMichael, a primitive logical relation of *inclusion* can hold between properties and relations. Because it is a primitive, it cannot be defined, but, intuitively, in the case of properties, the idea is that one property **P** includes another **Q** just in case, necessarily, anything that has **P** has **Q**. Thus, the property **being red** includes the property **being colored**. Again, intutively once again, one binary relation **R** includes another **R′** just in case, necessarily, for any objects **x** and **y**, if **x** bears **R** to **y**, then **x** bears **R′** to **y**. So, for example,the conjunctive relation **being both a child and an heir of** includes the relation **being a child of**.

Inclusion can also hold between an *n*+1-place relation and an *n*-place relation, relative to one of the argument places of the former.[6] Thus, in particular, a 2-place relation **Q** can include a property **P**, relative to one of its two argument places: intuitively, **Q** includes **P**, relative to its first argument place, if

and only if, necessarily, whenever two things **a** and **b** stand in the relation **Q**, **a** exemplifies **P**. And if the inclusion were with respect to the second argument place, of course, it would be **b** that exemplifies **P**. So, for example, the **child-of** relation, relative to its first argument place, includes the property **being a child of something**; whenever any object **a** bears the **child-of** relation to some object **b**, **a** has the existentially quantified property **being a child of something**. Similarly, **child-of** includes the property **being a parent of something** relative to its second argument place.

A (unary) role is just a "purely qualitative" property of a certain sort, where (as described in more detail in the supplementary document on Qualitative Essences) a purely qualitative property is a property that "involves" no particular individuals. Thus, such properties as **being a philosopher** and **being someone's mother or maternal aunt** are purely qualitative, while **being a student of Quine** and **being Johnson's mother or a friend of Boswell** are not. Given this, McMichael defines a property **P** to be a *unary role* if (i) it is exemplifiable, (ii) it is purely qualitative, and (iii) for any purely qualitative property **Q**, either **P** includes **Q** or **P** includes the complement **-Q** of **Q**. A role is thus a complete (nonmodal) "characterization" of the way something could be, qualitatively. Intuitively, then, the role of a given object is a "conjunction" of all of the purely qualitative, nonconjunctive properties the object exemplifies. Thus, for example, Socrates' role includes the properties **being a philosopher**, **being snub-nosed**, **being the most famous teacher of a famous philosopher**, **being condemned to death** and so on.[7] The notion of role generalizes in a natural way to all *n*-place relations, including, notably, propositions (i.e., 0-place relations) and binary (i.e., 2-place) relations. Thus, the binary role that Boswell bears to Johnson is, intuitively, a conjunction of all of the purely qualitative, nonconjunctive binary relations that Boswell bears to Johnson.[8] As one might suspect, it can be shown on McMichael's theory that a binary role includes a unique unary role with respect to each of its argument places. In particular, the binary role that Boswell bears to Johnson includes Boswell's unary role relative to its first argument place and Johnson's relative to its second.

Now (as also explained in the supplementary document on Qualitative Essences), Adams [1979] has argued persuasively that no purely qualitative property, no matter how complex, can serve as an individual essence for a contingent being. Hence, in general, roles -- being purely qualitative -- are not individual essences. Rather, they are general properties that are (in general) exemplifiable by different things (though not necessarily things in the same possible world). Because of this, none of the objections to Plantinga's haecceities is relevant to roles, as the fact that haecceities are individual essences lies at the heart of those objections. At the same time, McMichael is able to provide a semantics for (9) that does not run afoul of the iterated modalities objection. The basic trick is to

> ...alter the criterion for deciding what an individual might have done. Instead of saying that what an individual might have done is what *he* does in some possible world, let us say that what an individual might have done is what *any such* individual does in some possible world....To determine what Socrates might have done, we don't look for worlds in which he appears, but instead we look for roles in possible worlds which are accessible to Socrates' actual role. If one of these roles includes a certain property, then that property is one Socrates could have had; otherwise, it is not [ibid, 73].

Thus, a little more formally, where F is the property **being foolish**, and s is Socrates, a simple modal sentence such as

(21) Possibly, Socrates is foolish ($\Diamond Fs$)

is true just in case some unary role accessible to the actual role of Socrates includes the property of being foolish.

Similar to Plantinga's semantics, then, quantifiers do not range over individuals, but over roles. This enables McMichael to avoid the iterated modalities objection and provide a compositional semantics for our iterative paradigm (9). Specifically, (9) is true if and only if

(22) Some role **R** accessible to Wojtyla's actual role $\mathbf{R_k}$ includes the property **being a parent of someone** (i.e., the property [$\lambda y\ \exists xCxy$] expressed by the open formula ‘$\exists xCxy$’).

(22) captures the idea that an individual *such as* Wojtyla could have been a parent. Adams, of course, got this far in his account of (9). But, unlike Adams, with roles at his disposal, McMichael can continue his analysis of (9) and unpack the existentially quantified formula ‘$\exists xCxy$’. Specifically, (22) holds if and only if

(23) Some binary role **S** that includes the **child-of** relation (i.e., the relation expressed by the atomic formula ‘Cxy’) also includes, relative to its second argument place, the role **R** (a role accessible to Wojtyla's actual role $\mathbf{R_k}$).

That is, in accordance with McMichael's recursive definition of truth, (23) unpacks the quantified formula ‘$\exists xCxy$’ in terms of the **child-of** relation that is expressed by the embedded atomic formula ‘Cxy’. Specifically, the truth of (9) consists in the existence of a binary role **S** that includes the **child-of** relation and, relative to its second argument place, a role accessible to Wojtyla's role $\mathbf{R_k}$. Note that, being a binary role, **S** also includes a unique role relative to its first argument place. And because it includes the **child-of** relation and, relative to its second argument place, a role **R** accessible to Wojtyla's role $\mathbf{R_k}$, **S** will include, relative to its first argument place, a role $\mathbf{R'}$ that can only be exemplified by a child of whatever exemplifies **R**, i.e., a child of *such* an object as Wojtyla.

To capture the intuition that no such child could be identical to any actually existing thing, then, McMichael can simply deny that the role $\mathbf{R'}$ that would be exemplified by such a child is accessible to the role of any actually existing thing.

Problems with this Account

Objections to McMichael's role theory are addressed in the document Problems with the Actualist Accounts.

Dispensing with Worlds

A rather different approach to the possibilist challenge is broached by Menzel [1990]. This approach is clarified and refined by Ray [1995], and a very similar approach is elaborated in great formal and philosophical detail by Chihara [1998]. For ease of reference, call this the "no-worlds" approach.

All non-skeptical approaches to modality agree that Kripke models provide key insights into the meaning of our modal discourse and the nature of modal reality. However, as we have seen, the naive "intended" model of Kripke semantics leads to possibilism. The standard actualist response -- following David Lewis, "ersatzism" -- has been to define actualistically acceptable notions of possible worlds and possible individuals to serve as replacements for the elements of **W** and **D** in the naive intended model, thereby (or so it is argued) preserving the semantical and metaphysical benefits of Kripke models while avoiding ontological commitment to *possibilia*. As just seen above, however, ersatzism is still problematic. By contrast, the no-worlds account does not attempt to identify worlds as acceptable abstract entities of some sort. Rather, the notion of a possible world is abandoned altogether.

To get at the idea, note first that the notion of an intended Tarski model makes perfectly good sense for a formalization of nonmodal discourse about the actual world. To illustrate, suppose we have a given a piece of nonmodal discourse about a certain event, a baseball game, say. Suppose now we formalize that discourse in a nonmodal language L'; that is, for each referring expression in the disourse (e.g., ‘Mark McGwire’, ‘second inning’, etc.), there is a unique constant of L', and for every simple verb phrase in the discourse (‘is a home run’, ‘is out’, ‘relieves’, etc.) there is a unique predicate of L'. Then we can form a Tarski model $\mathbf{M}_{L'}$ for L' whose domain consists of the actual objects that the speakers are talking about in the discourse (fans, players, equipment, etc.) and which interprets the predicates of L' so that they are true of exactly those (*n*-tuples of objects in the domain that are in the extension of the corresponding verb phrases of the discourse. In this way we form the intended model of L', the piece of the world that it is intended to be about.

According to proponents of the no-worlds account, the fallacy of both ersatzism and possibilism is the inference that things must work in largely the same way with regard to Kripke models. A Kripke model is basically an indexed collection of Tarski models. Just as there is an intended Tarski model for a nonmodal language L' constructed from the actual world, the accounts above infer that, for a given formalization L of modal discourse, there must be an intended Kripke model constructed from all possible worlds. And, depending on one's tolerance for possibilia, this leads either to possibilism or one of its ersatz variations.

For no-worlders, the modal upshot of a Kripke model lies in its structure rather than its content. The specific elements of a Kripke model are irrelevant. Rather, under appropriate conditions, it is the form of a Kripke model alone that tells us something about modal reality. Specifically, the model theory of Kripke semantics is retained in the no-world account. The elements of a model are irrelevant; it is easiest

just to take them to be pure sets, or ordinal numbers, or some other type of familiar mathematical object. Consequently, there can be no notion of a single intended model, because, for every model, there are infinitely many others that are structurally isomorphic to it, and structure is all that matters on the no-worlds account. In place of intended models, the no-worlds account offers the notion of an *intended** model. To get at the idea, suppose one has an intended Tarski model **M** of the actual world, a model that actually contains entities in the world and assigns extensions to predicates that reflect the actual meanings of the adjectives and verb phrases those predicates formalize. Now replace the objects in that model with abstract objects of some ilk to obtain a new model $\mathbf{M'}$ that is structurally isomorphic to **M**. Then $\mathbf{M'}$ also models the world under a mapping, or embedding, that takes each element $\mathbf{e'}$ of $\mathbf{M'}$ to the element **e** that it replaced in **M**. We can thus justifiably think of $\mathbf{M'}$ as a sort of intended model because, even though it doesn't necessary *contain* anything but pure sets (or some other type of mathematical object), under an appropriate embedding it models the actual world no less than **M**. To distinguish models like $\mathbf{M'}$ that require a nontrivial embedding into the world from models like **M**, we call the former *intended** models.

For no-worlders, the notion of an intended* Tarski model is all that is needed for modeling the modal facts. From these a notion of an intended* Kripke model can be defined. Assume that **L** is a model language that formalizes some range of modal discourse about the world. Roughly, then, an intended* Kripke model **M** is simply a Kripke model such that (i) the Tarski model indexed by the distinguished index $\mathbf{w_0}$ is an intended* Tarski model of the actual world, (ii) every Tarski model $\mathbf{M'}$ in **M** *could have been* an intended* model of the world, that is, the world could have been as $\mathbf{M'}$ represents it, and (iii) necessarily, some Tarski model in **M** is an intended* model of the world, i.e., no matter how the world had been, there would have been an intended* Tarski model of it in **M**.[9]

Truth in a model on the the no-worlds account is defined as usual as truth at the distinguish index $\mathbf{w_0}$ of the model, hence, a sentence φ is true simpliciter if and only if it is true at the distinguished index of some (hence, any) intended* Kripke model. Given the definition of an intended* model, it follows that a modal formula '$\Diamond\varphi$' is true if and only if, for some intended* Kripke-model **M**, φ is true in some Tarski-model $\mathbf{M'}$ in **M**, that is, in some Tarski-model $\mathbf{M'}$ in **M** that could have been an intended* model of the world. Thus, in particular, (1) is true if and only if

> (20) For some intended* Kripke model **M**, there is a Tarski model $\mathbf{M'}$ in **M** in which '$\exists xAx$' is true,

that is, given the definition of an intended* Kripke model, if and only if there is a Tarski model $\mathbf{M'}$ that could have been an intended* Tarski model and such that, if it had been, there would have been Aliens.

For the no-worlder, then, intended* Kripke models adequately represent the modal structure of the world simply by virtue of their own modal properties. Since Kripke models are constructed entirely out of existing objects, the semantics for modal logic requires no distinction between what is actual and what is possible. It therefore conforms with the thesis of actualism, but does so without the elaborate metaphysical apparatus of the ersatzers.

Problems with this Account

Objections to the no-world account are addressed in the document Problems with the Actualist Accounts.

An Actualist Interpretation of the Simplest QML

Finally, we consider to a new form of actualism that has been proposed recently. This form of actualism refocuses our attention on the Simplest Quantified Modal Logic (SQML) and offers a way to reinterpret this formalism to eliminate its apparent commitment to *possibilia*. On this form of actualism, the truth conditions for the modal claim "There might have been Aliens" are just what they appear to be, namely, that in some possible world, there is an object that is an Alien at that world. However, these truth conditions do not commit us to possibilia. Instead, the new form of actualism is based on the idea that these truth conditions are committed only to the existence of *nonconcrete* objects which might have been Aliens. This theory has been recently put forward by Linsky and Zalta ([1994] and [1996]) and Williamson ([1998] and [1999]), though Williamson simply eschews the word ‘actual’ in his formulation of the theory. These philosophers claim that the nonconcrete objects in question are not Aliens, but instead have the modal property of possibly being an Alien. In other words, modal claims such as "There might have been Aliens" (formalized, once again, as (1)) can be interpreted to be true in virtue of the *actual* existence of objects that are nonconcrete (and hence which are not Aliens) at our world, but which are Aliens (and hence concrete) at some other possible world. Thus, the nonconcrete objects involved in the truth conditions of such modal claims do exist and are actual. To say this is to use a sense of "existence" and "actual" similar to that used by Platonists when they claim that mathematical objects exist and are actual. However, unlike mathematical objects, which are nonconcrete at *every* possible world, the actual objects required by the truth of modal claims are only *contingently* nonconcrete -- they are nonconcrete at our world but concrete at other possible worlds. Similarly, ordinary concrete objects (like the rocks, tables, planets, etc., of our world) are assumed to be contingently concrete--they are concrete at some worlds (including ours) and not at other worlds.

With this basic idea in hand, the ‘new actualists’ point out that our ordinary modal claims can be given a straightforward analysis by: (1) regimenting ordinary modal discourse in the simplest possible way using the language and logic of the simplest quantified modal logic (SQML) and (2) semantically interpreting SQML by appealing to contingently concrete objects and contingently nonconcrete objects (both of which are assumed to actually exist). This interpretation, the new actualist argues, reveals that the problematic theorems of SQML -- most notably, the Barcan Formula (BF), the Converse Barcan Formula (CBF), and the Necessary Existence (NE) theorems -- do not contradict our modal intuitions, once those intuitions are understood in terms of a more subtle conception of the abstract/concrete distinction.

To see why, reconsider the definition and discussion of SQML and reexamine BF. From the fact that there might have been aliens ($\Diamond\exists xAx$), BF requires only that there exist something that *could have been* an Alien ($\exists x\Diamond Ax$). But, it was asked, doesn't this contradict the intuition (described at the very outset) that *nothing could have been an Alien*? Here, the new actualist argues that this intuition is true only when it is properly understood as the intuition that *no concrete object could have been an Alien*. Recall our

thought experiment at the outset, which asked us to "imagine a race of beings that is very different from any life-form that actually exists anywhere in the universe; different enough, in fact, that no actually existing thing could have been an Alien, any more than a given gorilla could have been a fruitfly." The relevant intuition, that nothing could have been an Alien, is grounded in the fact that when we look around us and examine all the concrete objects that there are, we note that none of those objects could have been an Alien (just as no gorilla could have been a fruitfly). However, this leaves room to claim that there exist (contingently) *non*concrete objects which could have been Aliens. According to the new actualist, these contingently nonconcrete objects have been overlooked because (1) no one has correctly drawn the proper distinction between contingently nonconcrete and necessarily nonconcrete objects, and (2) everyone has assumed that concreteness was an *essential* property of concrete objects (see below).

Thus, according to the new actualist, whenever there is a true claim of the form "There might have been something which is *F*", BF doesn't imply anything that is incompatible with our modal intuitions. For the conclusion that it forces, namely, that "There exists something that might have been an *F*", does not require us to suppose that there is some concrete object which might have been *F*. BF need only require the existence of contingently nonconcrete objects which might have been *F*. Similar reasoning is developed in the supplementary document Why CBF and NE Are Harmless Consequences of SQML.

Once it is seen that BF requires only contingently nonconcrete objects and not possibilia, it is natural to reconceive the nature of concrete objects. According to new actualism, ordinary concrete objects are concrete at some worlds and not at others. This is the sense in which they are contingent objects. Traditional actualists have described worlds where these objects are not concrete as worlds where these objects don't exist or have any kind of being. By contrast, the new actualist just rests with their nonconcreteness at the world in question, and argues that that should suffice to account for our intuition that such objects "are not to be found" in such a world. Moreover, new actualists reconceive the idea of an "essential" property of a concrete object. Instead of saying that Socrates is essentially a person because he is a person in every possible world where he exists, new actualists say that he is essentially a person because he is a person in every world where he is concrete.

So by recognizing the existence of contingently nonconcrete objects and by reconceiving both the contingency of concrete objects and the notion of an essential property in what seem to be harmless ways, there appears to be a way to interpret SQML so that it is consistent with actualism. Specifically, in the "intended" new actualist model, everything in the one domain **D** both exists and is actual. **D** includes: (1) (contingently) concrete objects, (2) necessarily concrete objects (if there are such), (3) contingently nonconcrete objects, and (4) necessarily nonconcrete objects (if there are such). All of these objects in **D** are said to actually exist.

New actualism appears to lack the awkward features that plague other forms of actualism. In contrast to Kripke's System, the metalanguage does not quantify over possibilia and object language quantifiers can range over everything the metalanguage quantifiers range over. In contrast to Prior's approach, no distinction between two kinds of necessity is needed. In contrast to Plantinga's haecceitism, there is an objectual interpretation of quantified modal logic which is expressible in terms of the basic notion of an individual exemplifying properties (rather than in the less basic terminology of coexemplification). In

contrast to Adams' world story approach, there is no puzzle arising from propositions which do not exist at worlds where their constituents do not exist--propositions and their constituents exist necessarily, though the contingent constituents of propositions fail to be concrete at some worlds. In particular, all objects exist necessarily for the new actualist, and hence can be quantified over relative to any possible world, it should be clear that the new actualist has no trouble with the semantics of iterated modalities. (Details are provided in the supplementary document New Actualism and Iterated Modalities for the interested reader.) In contrast to Fine's world propositions approach, object language modal operators are fully interpreted in terms of worlds alone, and hence can be thought of as providing a genuine semantical analysis of the modal operators -- although, admittedly, this will depend on a conception of worlds that does not itself involve a primitive notion of propositional possibility. At the least, the account provides as much explanatory power as Fine's in a manner that is both ontologically simpler and more direct. In contrast to McMichael's role theory, modal truths such as "Socrates might have been a carpenter" are genuinely about Socrates. In contrast to the no-worlders, the idea that necessary truth is truth in all possible worlds is preserved. The intended interpretation has in its domain all of the objects that actually exist and extensions can be distributed to properties at the various worlds in just the way that is required by the modal facts. Modal discourse, then, is directly about an independent reality free of possibilia, and the relationship between the formal language and the intended model exactly mirrors the relationship between ordinary modal language and the reality that grounds modal truth.

Notes to Actualism

Notes

1. Some good sources for actualism are the following: Adams [1974], Plantinga [1976], Kaplan [1975], Loux [1979], and Tomberlin and van Inwagen [1985].

2. We assume here that, as with all natural kinds, being an Alien is an essential property of anything that has it.

3. A potential actualist move is worth addressing here. One might argue that, in fact, there is a straightforward actualist account of the possibility of Aliens. A widely-accepted contemporary metaphysical belief is that, for every set of objects, there exists the mereological sum consisting of exactly those objects. Given this, assuming that Aliens are composed of the same basic atomic stuff that we are, there are surely actual merological sums of atoms that are possible Aliens, i.e., that *could* have been Aliens if only they'd been properly arranged. Hence, there is no need to postulate possibilia to provide a semantics for claims like ‘It is possible that there are Aliens’. However, this objection misses the point. The general intuition that we are attempting to isolate with the Alien example is that

> (*) *There could have been things other than the things that actually exist*.

All that the actualist move just noted succeeds in showing is that perhaps the Alien example doesn't entail (*). But it does not succeed in accounting for the intuition that (*) is true. For suppose we accept the proposed mereological gambit, i.e., that certain mereological sums of actual atoms could have been Aliens, or instances of any other uninstantiated natural kind. Is it not still the case that there could have been *different atoms* (or quarks or whatever basic building blocks you choose) than there are in fact? Indeed, is it not logically possible that the universe could have been composed of entirely different stuff altogether? If so, then the actualist still needs to account for (*).

It should also be noted that the mereological gambit itself is dubious. Its basic premise -- that any collection of atoms constitutes a further physical object -- is far from uncontroversial. More seriously, it seems quite clear that no instance of a physical natural kind *is* identical with any given mereological sum of atoms, as physical bodies are constituted by many different sums of atoms across time as those bodies change. Perhaps, however, the actualist could come up with some more sophisticated mereological construct C to avoid this objection. Still, it seems, there are problems. For intuitively, it seems that the same C, structured one way, could have been an instance of one kind, and structured another, could have been an instance of a different kind. But then it seems to follow from the "modal transitivity" of identity (i.e., the principle:

$$\forall x \Box \forall y(y{=}x \rightarrow \Box \forall z(x{=}z \rightarrow y{=}z)))$$

that if a member of a natural kind is literally identical with a C, then it is possible that an instance of a given kind could have been an instance of a very different kind. But this conflicts with strong intuitions about the essentiality of kind membership. So even if the actualist's hypothetical construct C were plausible, rather than taking Cs to be actualist surrogates for possible Aliens (or whatever), it would be at least equally reasonable to claim that certain Cs are only possibly *co-located* with, or possibly *constitutive of*, but not possibly identical with, an Alien. For, in that case, all that follows is that the same C might have been co-located with (or constitutive of) instances of very different natural kinds, and intuitions about the essentiality of kind membership are preserved.

4. Unfortunately, for reasons rooted ultimately in the monumental work of Gödel [1931], a first-order logic cannot provide a completely *decidable* mechanism for determining validity. More exactly, while it is true that, if a formula is valid, one can eventually find a proof of it in the logic, there is in general no proof theoretic way to determine that a formula is *invalid*.

5. Adams [1974], p. 204. This is equivalent to the following, simpler definition: a world story is a set **s** of propositions such that it is possible that, for all propositions **p**, **s** contains **p** if and only if **p** is true. This account of world stories is significantly more accessible than the later account in Adams [1981]. The added subtleties of the later account are introduced to enable it to serve as a semantics for a broader range of modal statements, particular those involving contingent propositions, notably propositions about possible nonexistence. However, for the purposes of the present article, these subtleties add unnecessary complexity, as I believe that the 1981 account ultimately falls prey to essentially the same objections that are raised here against the earlier account.

6. McMichael does not actually use the idea of inclusion relative to an argument place. Rather, I have introduced it to simplify the presentation of the theory. It is an equivalent mechanism and so has no impact on the theory's content. McMichael's own account relies on an elegant, but conceptually more challenging permutation mechanism that shuffles argument places in relations.

7. For the sake of simplicity, we ignore temporal qualifications in these examples that would be needed in a fully accurate account, e.g., **being condemned to death as an adult**.

8. As indicated, order matters in our representation of relations: the binary role that Boswell bears to Johnson is distinct from the binary role that Johnson bears to Boswell, the latter, of course, being the converse of the former.

9. Things are a bit more subtle than this, for to have an intended* model, one also needs to do a little more to reflect the modal facts expressed by means of iterated modalities. See Menzel (1990) for details.

Supplement to Actualism

Three Types of Possibilism

A possibilist is someone who believes that there are things that are not actual. There are two ways to understand this claim. On the first, the possibilist distinguishes *what there is* from *what exists, or is actual*, and argues that the latter comprises a relatively small portion of the former. On this view, then, actual things exhibit a certain intrinsic, ontological property --- *existence*, or *actuality* --- which things that merely *are* happen to lack, things like Aliens, people that were never born, and so on. Such things *could* have exhibited this property, of course, and indeed would have had things been different, but, as it happens, they simply do not. This, then, on the first understanding of possibilism, is what the possibilist means when she says that there are things that are not actual.

The second way of understanding possibilism can be traced back to Quine [1948], who insisted that there is no coherent distinction between what there is and what exists. Thus, for Quine, possibilism, as understood in the previous paragraph, is straightforwardly inconsistent. For to say ‘there are things that don't exist’ would simply be to say ‘there exist things that don't exist’. He left a loophole, however, that allows a possibilist to skirt Quine's charge. Rather than distinguishing being from existence, the possibilist can agree with Quine that they are identical: everything there is exists. However, the possibilist will insist, not everything that exists is *actual*. To say that there are things that are not actual, then, is to say that there *exist* things that fail to be actual.

One might charge that this second variety of possibilist is playing mere word games: she has retained the metaphysics of classical possibilism, but has simply renamed being as ‘existence’ and existence as ‘actuality’. And indeed, that is perhaps the most natural way of construing the move -- the possibilist agrees to cede Quine's point about the comprehensiveness of the meaning of ‘existence’. The possibilist's rejoinder is that Quine's point is no threat to the coherence of a possibilist metaphysics.

Quine, of course, would likely reply that the wedge driven by this new variety of possibilism between existence and actuality is no more legitimate than the one formerly driven between being and existence. Thus, for Quine, the possibilist has not really addressed the original objection, which challenges the possibilist's introduction of two modes of being. The possibilist has simply replaced two modes of being with two modes of existence --- actual existence and possible existence. Again, though, the possibilist is not without a reply: she can simply deny that actuality is any sort of ontological mode. It's just a property that some things have, and other things lack. The debate at this point seems a stalemate.

There is one final notable form of possibilism that is truer in spirit to Quine's original objection, namely, David Lewis's. As with the second form of possibilism just discussed, on Lewis's view, being and existence coincide; there is no special ontological property, no distinct mode of being, that separates

merely possible objects from actual ones. Moreover, as with the second form, actuality does not coincide with existence. However, unlike the second form, actuality is not any sort of intrinsic ontological property. Indeed, actuality is not really a property at all, but a *relation*: *x* is actual relative to *y* just in case *x* and *y* occupy the same possible world; or, equivalently, just in case they are spatially or temporally related to one another. (*x* is spatially related to *y* just in case *x* and *y* occupy the same space or some distance separates them. Similarly, *x* is temporally related to *y* just in case *x* and *y* exist at exactly the same times or one existed at some time before or after the other.) On this view, then, to say that there are things that are not actual is simply to say that there are things that occupy other worlds than ours, things that exist, in a fully-fledged sense, but which are just spatially and temporally unrelated to *us*.

Lewis proposes a well-known, and natural, semantic corollary to this view about actuality, namely, that the word ‘actual’ is an *indexical*: its reference on any given occasion of utterance, like that of ‘I’, ‘now’, etc., is essentially determined by the context of the utterance, and in particular, the world in which the utterance occurs. Thus, what makes "Clinton is actual" (or, somewhat more naturally, "Clinton actually exists") true when I utter it is not some intrinsic property of Clinton --- actuality --- but rather simply the fact that he occupies the same world as the speaker, i.e., me.

As with the second version of possibilism, then, Lewis acknowledges the comprehensive character of existence, but without introducing any special primitive property, or existential mode, of actuality. Either way, modern day possibilists are able to follow Quine in rejecting the distinction between being and existence and still make sense of both possibilism and modality generally.

An Account of Abstract Possible Worlds

As an example of actualistically acceptable abstract worlds, we draw chiefly upon Plantinga's account. In this account, we replace the possibilist idea of merely possible worlds with that of a certain type of *state of affairs* (alternatively, a certain type of proposition) which exists but fails to obtain (alternatively, fails to be true). Where propositions are said to be true or false, states of affairs are said to *obtain* or not. Say that one state of affairs *s includes* another s' if and only if it is not possible that *s* obtain without s' obtaining. Importantly, note that a state of affairs can exist without obtaining, just as a proposition can exist without being true. States of affairs, like propositions, are taken to be necessary beings on this account.

We can now define several critical notions:

- A state of affairs *w* is a *world* just in case it is possible that *w* includes all and only states of affairs that obtain.
- For any state of affairs *s* and world *w*, *s obtains at w* just in case *w* includes *s*.
- A world *w* is *actual* just in case *w* obtains.
- An individual *x exists in* world *w* just in case the state of affairs *x's existing* obtains at *w*.

This theory is then to be applied as follows. The everyday claim ‘it is possible that there are Aliens’ can then be analyzed as: the state of affairs *There are Aliens* obtains at some world (i.e., there is some world, in the above sense of ‘world’, which implies that there are Aliens). If there are no Aliens, then no such world obtains. Similarly, an ordinary claim of the form ‘it is necessary that *p*’ can be analyzed as: *p* obtains at every possible world. Thus, in this first stage of the actualist treatment of modality, ordinary possibility claims are analyzed in terms of actually existing states of affairs. This step is, therefore, consistent with Thesis (A). So far, no possible-but-nonactual objects have been introduced for the analysis of modal claims.

In putting forward this theory, the actualist takes herself to be replacing an obscure distinction between two modes of being -- possible existence and actual existence -- with an intelligible distinction. This distinction is replaced by an allegedly clear distinction between two kinds of existing states of affairs -- those that obtain and those that don't). That the latter distinction is more intelligible than the former ones is often just assumed by the actualist without argument. This invites the question whether there are cogent arguments for this assumption. However, again, we will not pursue this question here.

Furthermore, in putting forward this theory, the actualist has not invoked any objects which have such

modal properties as being a possible million carat diamond, being a possible talking donkey, being a possible Alien, etc. The ‘worlds’ of the actualist do in fact have modal properties and the fact that they do is essential for them to do the work they have to do in the theory. A possible world is a state of affairs that *could* be such that it includes all and only states of affairs that obtain. Postulating objects with modal properties such as this seems less objectionable to the actualist than postulating objects with the modal properties described at the beginning of this paragraph. This of course invites a certain question, namely, just why is it less objectionable to have objects with the latter modal properties than the former one. But, again, we will not pursue this question here.

This latter point about the actualist theory of worlds brings us to the second step of their treatment of modality, namely, how to analyze ordinary modal claims that seem to require such possible individuals as possible million carat diamonds, possible talking donkeys, possible Aliens, etc. For the remainder of this essay, then, we assume that some actualist theory of worlds is viable and therefore concentrate our energies solely on the problems that arise in connection possible individuals rather than possible worlds.

Background Assumptions for Plantinga's Account

There are several background assumptions that are required for Plantinga's solution to be adequate

> (P1) Worlds are (maximal possible) states of affairs.

That is, Plantinga adopts the approach sketched in the supplementary document An Account of Abstract Possible Worlds on which possible worlds are abstract states of affairs that actually exist but (in general) don't obtain. Plantinga thus avoids the first aspect of the possibilist challenge.

> (P2) Properties are "first-class citizens"; that is, they are legitimate objects of reference and (first-order) quantification;

If individual essences are to play the role that possibilia play in Kripke's account, then, clearly, it must be possible to quantify over them directly with first-order quantifiers. Plantinga is a platonist --- properties, propositions, and states of affairs are as real as any concrete particular, it's just that they are abstract. Hence, they can be quantified over no less than their concrete counterparts. The advantages of this move are clear. As noted above, Kripke's account fails to be actualist because it quantifies over possibilia in the metalanguage. By replacing possibilia with individual essences, quantifiers range over essences, and hence only over actually existing things.

> (P3) Properties, propositions, and states of affairs all exist necessarily.

As noted in the main document, unlike (most, at least) concrete particulars, properties are necessary beings for Plantinga; it is not possible that there be a property that might fail to exist. Consequently, necessarily, any property that exists in any possible world exists in all possible worlds. (That is, in terms of Plantinga's actualist reconstruction of worlds, necessarily, if a property's existence is entailed by any possible world, it is entailed by all possible worlds.) It follows, in particular, that individual essences are necessary beings.

Why is (P3) needed? After all, in general, not all possibilia exist in every possible world in Kripke's semantics and hence, it would seem, they are not necessary beings; more formally, NE is not a logical truth in Kripke's system. However, the fact that NE fails in Kripke's theory is simply an artifact of his semantics for the quantifiers --- quantifiers at a given world **w** range only over the things that exist in **w**, and hence, that NE is not a logical truth in Kripke's system only reflects the fact that not all possibilia exist *in*, i.e., are *actual* in, every possible world. However, all possibilia are in a clear sense *there* at each

world all the same; Kripke could just as easily have defined the semantics of the quantifiers so that they ranged over all of them. (Indeed, in his original model theory, a 1-place predicate at a world **w** can have possibilia that do not exist in **w** in its extension.) He chose not to define the semantics of the quantifiers in this way simply to avoid validating BF, CBF, and NE and thus to have at least an actualistically acceptable proof theory. Thus, although there is no object language theorem expressing that possibilia are necessary beings, this is clearly an important metaphysical consequence of his semantics, and hence it needs to be reflected in Plantinga's solution.

The necessity of individual essences is still not enough, though. For if individual essences are to replace possibilia, then we must be assured that there are enough of them, that, crudely put, for "every possible individual" there is a corresponding individual essence. This is guaranteed by the following principle:

> (P4) Necessarily, every object has an individual essence.

A First-Order, Quantified Modal Language

Primitive Vocabulary:

Terms:

Individual Constants: $a, b, c, \ldots$

individual Variables: $x, y, z, \ldots$

Predicates: $P^n, Q^n, R^n, \ldots \quad (n \geq 0)$

Atomic Formulas:

1. If $\tau_1, \ldots, \tau_n$ are any terms and ρ^n is any predicate, then $\rho^n \tau_1 \ldots \tau_n$ is an atomic formula. ('$\tau_1, \ldots, \tau_n$ exemplify ρ^n')
2. If τ_1 and τ_2 are any terms, then $\tau_1 = \tau_2$ is an atomic (identity) formula. ('τ_1 is identical to τ_2')

Formulas:

1. All atomic formulas are formulas.
2. If φ is a formula, then so is $\neg\varphi$. ('it is not the case that φ')
3. If φ and ψ are formulas, then so is $\varphi \rightarrow \psi$. ('if φ, then ψ')
4. If φ is a formula, and α is any variable, then so is $\forall\alpha\varphi$. ('every object α is such that φ')
5. If φ is a formula, then so is $\Box\varphi$. ('it is necessary that φ')

Definitions:

$$\varphi \,\&\, \psi \;=_{df}\; \neg(\varphi \rightarrow \neg\psi)$$

$$\varphi \,\&\, \psi \;=_{df}\; \neg(\varphi \rightarrow \neg\psi)$$

$$\varphi \vee \psi \;=_{df}\; \neg\varphi \rightarrow \psi$$

$$\varphi \equiv \psi \;=_{df}\; (\varphi \rightarrow \psi) \,\&\, (\psi \rightarrow \varphi)$$

$$\exists\alpha\varphi \;=_{df}\; \neg\forall\alpha\neg\varphi$$

$$\Diamond\varphi \;=_{df}\; \neg\Box\neg\varphi$$

The Simplest Semantics for a Quantified Modal Language

Interpretations: An interpretation $\mathbf{I}$ is any quadruple $\langle \mathbf{W}, \mathbf{w}_\alpha, \mathbf{D}, \mathbf{V} \rangle$ defined as follows: (1) $\mathbf{W}$ is a non-empty domain of possible worlds. (2) $\mathbf{w}_0$ is a distinguished member of $\mathbf{W}$ (the actual world). (3) $\mathbf{D}$ is a non-empty domain of individuals. (4) $\mathbf{V}$ is a function assigning semantic values to the constants and predicates as follows: (a) $\mathbf{V}(\tau) \in \mathbf{D}$, and (b) $\mathbf{V}(\rho^n) \in [\mathcal{P}(\mathbf{D}^n)]^{\mathbf{W}}$; i.e., $\mathbf{V}$ both (a) assigns each constant τ to an element of the domain $\mathbf{D}$ and (b) assigns to each n-place predicate ρ^n a function which maps each possible world $\mathbf{w}$ (supplied as an argument) to the set of n-tuples that ρ^n applies to at $\mathbf{w}$.

Assignments to Variables and the Denotation Function: (1) An *assignment* to the variables is any function $\mathbf{f}$ which maps each variable to a member of the domain $\mathbf{D}$. (2) If given an interpretation $\mathbf{I}$ and assignment function $\mathbf{f}$, we define *the denotation of* term τ *with respect to* interpretation $\mathbf{I}$ *and* assignment $\mathbf{f}$ ('$\mathbf{d}_{\mathbf{I},\mathbf{f}}$') as follows: (a) If τ is a constant, then $\mathbf{d}_{\mathbf{I},\mathbf{f}}(\tau)$ is $\mathbf{V}(\tau)$, and (b) If τ is a variable, then $\mathbf{d}_{\mathbf{I},\mathbf{f}}(\tau)$ is $\mathbf{f}(\tau)$.

Truth$_{\mathbf{I},\mathbf{f}}$ at a World (φ *is true*$_{\mathbf{I},\mathbf{f}}$ *at* $\mathbf{w}$):

(1) $\rho^n\tau_1 \ldots \tau_n$ is true$_{\mathbf{I},\mathbf{f}}$ at $\mathbf{w}$ iff $\langle \mathbf{d}_{\mathbf{I},\mathbf{f}}(\tau_1), \ldots, \mathbf{d}_{\mathbf{I},\mathbf{f}}(\tau_n) \rangle \in [\mathbf{V}(\rho^n)](\mathbf{w})$.
(2) $\tau_1 = \tau_2$ is true$_{\mathbf{I},\mathbf{f}}$ at $\mathbf{w}$ iff $\mathbf{d}_{\mathbf{I},\mathbf{f}}(\tau_1) = \mathbf{d}_{\mathbf{I},\mathbf{f}}(\tau_2)$.
(3) $\neg\psi$ is true$_{\mathbf{I},\mathbf{f}}$ at $\mathbf{w}$ iff ψ fails to be true$_{\mathbf{I},\mathbf{f}}$ at $\mathbf{w}$.
(4) $\psi \rightarrow \chi$ is true$_{\mathbf{I},\mathbf{f}}$ at $\mathbf{w}$ iff either ψ fails to be true$_{\mathbf{I},\mathbf{f}}$ at $\mathbf{w}$ or
χ is true$_{\mathbf{I},\mathbf{f}}$ at $\mathbf{w}$.
(5) $\forall x\psi$ is true$_{\mathbf{I},\mathbf{f}}$ at $\mathbf{w}$ iff for every $\mathbf{f}'$, if $\mathbf{f}' \stackrel{x}{=} \mathbf{f}$, then ψ is true$_{\mathbf{I},\mathbf{f}'}$ at $\mathbf{w}$.[1]
(6) $\Box\psi$ is true$_{\mathbf{I},\mathbf{f}}$ at $\mathbf{w}$ iff for every $\mathbf{w}'$, ψ is true$_{\mathbf{I},\mathbf{f}}$ at $\mathbf{w}'$.

Truth$_\mathbf{I}$ at a World:

φ is *true*$_\mathbf{I}$ *at* $\mathbf{w}$ iff for every assignment $\mathbf{f}$, φ is true$_{\mathbf{I},\mathbf{f}}$ at $\mathbf{w}$.

Truth$_\mathbf{I}$:

φ is *true*$_\mathbf{I}$ iff φ is true$_\mathbf{I}$ at $\mathbf{w}_0$.

Logical Truth:

φ is *logically true* iff for every interpretation $\mathbf{I}$, φ is true$_\mathbf{I}$.

---

[1]The clause '$f' \overset{x}{=} f$' abbreviates the claim that f' is an assignment function just like f except perhaps for what it assigns to the variable x.

The Simplest Quantified Modal Logic

Propositional Logic:

Axioms: Tautologies of propositional logic

Rule of Modus Ponens (MP): if $\vdash \varphi \rightarrow \psi$ and $\vdash \varphi$, then $\vdash \psi$

Classical First-Order Quantification Theory:

Axiom: $\forall\alpha\,\varphi \rightarrow \varphi^{\tau}_{\alpha}$, where τ is any term substitutable for α

Axiom: $\forall\alpha(\varphi \rightarrow \psi) \rightarrow (\varphi \rightarrow \forall\alpha\,\psi)$, where α is not free in φ

Rule of Generalization (GEN): if $\vdash \varphi$, then $\vdash \forall\alpha\,\varphi$

Logic of Identity:

Axiom: $x = x$

Axiom: $x = y \rightarrow (\varphi(x,x) \rightarrow \varphi(x,y))$, where $\varphi(x,y)$ is the result of substituting y for some, but not necessarily all, occurrences of x in $\varphi(x,x)$, provided that y is substitutable for x at those occurrences.

S5 Modal Logic:

K Axiom: $\Box(\varphi \rightarrow \psi) \rightarrow (\Box\varphi \rightarrow \Box\psi)$

T Axiom: $\Box\varphi \rightarrow \varphi$

5 Axiom: $\Diamond\varphi \rightarrow \Box\Diamond\varphi$

Rule of Necessitation (RN): if $\vdash \varphi$, then $\vdash \Box\varphi$

NOTE: Both the Barcan Formula and the Converse Barcan Formula are derivable from the above:

BF: $\forall x\Box\varphi \rightarrow \Box\forall x\varphi$

$$\text{BF: } \forall x \Box \varphi \rightarrow \Box \forall x \varphi$$

$$\Diamond \exists x \varphi \rightarrow \exists x \Diamond \varphi \quad \text{(equivalent formulation)}$$

$$\text{CBF: } \Box \forall x \varphi \rightarrow \forall x \Box \varphi$$

$$\exists x \Diamond \varphi \rightarrow \Diamond \exists x \varphi \quad \text{(equivalent formulation)}$$

The 5 Axiom is Logically True

Proof: To see that the 5 axiom is true in every interpretation, pick an arbitrary interpretation **I**. To show that a conditional sentence is true$_{\mathbf{I}}$, the definition tells us that we must show that it is true$_{\mathbf{I}}$ at the actual world $\mathbf{w}_0$. To do this, we assume that the antecedent is true$_{\mathbf{I}}$ at $\mathbf{w}_0$ and then show that the consequent is true$_{\mathbf{I}}$ at $\mathbf{w}_0$. So assume that the antecedent of the 5 axiom, namely, $\Diamond\varphi$, is true$_{\mathbf{I}}$ at $\mathbf{w}_0$. It follows, by the definition of truth, that φ is true$_{\mathbf{I}}$ at some possible world, say $\mathbf{w}_1$. Now to show that $\Box\Diamond\varphi$ is true$_{\mathbf{I}}$ at $\mathbf{w}_0$, we need to show that $\Diamond\varphi$ is true$_{\mathbf{I}}$ at all possible worlds. So pick an arbitrary possible world, say $\mathbf{w}_2$. Note that $\Diamond\varphi$ is true$_{\mathbf{I}}$ at $\mathbf{w}_2$, since φ is true$_{\mathbf{I}}$ at $\mathbf{w}_1$. But since $\mathbf{w}_2$ was chosen arbitrarily, it follows that $\Diamond\varphi$ is true$_{\mathbf{I}}$ in all possible worlds. So $\Box\Diamond\varphi$ is true$_{\mathbf{I}}$ at the actual world.

The Barcan Formula is Logically True

Proof: To see that the Barcan Formula is true in every interpretation, pick an arbitrary interpretation **I**. To show that a conditional sentence is true$_{\mathbf{I}}$, the definition tells us that we must show that it is true$_{\mathbf{I}}$ at the actual world $\mathbf{w}_0$. To do this, we assume that the antecedent is true$_{\mathbf{I}}$ at $\mathbf{w}_0$ and then show that the consequent is true$_{\mathbf{I}}$ at $\mathbf{w}_0$. So assume that the antecedent of BF axiom, namely, $\Diamond\exists x\varphi$, is true$_{\mathbf{I}}$ at $\mathbf{w}_0$. It follows, by the definition of truth, that $\exists x\varphi$ is true$_{\mathbf{I}}$ at some possible world, say $\mathbf{w}_1$. It follows from this that some individual in the domain, say **i**, satisfies$_{\mathbf{I}}$ φ at $\mathbf{w}_1$. [This conclusion takes a few liberties with the definition of satisfaction, but no harm comes from employing this simpler manner of speaking as if individuals satisfied formulas at worlds rather than strictly speaking in terms of assignment functions satisfying formulas at worlds.] Therefore, **i** satisfies$_{\mathbf{I}}$ $\Diamond\varphi$ at $\mathbf{w}_0$. So, $\exists x\Diamond\varphi$ is true$_{\mathbf{I}}$ at $\mathbf{w}_0$.

The 'Necessary Existence' Principle is Logically True

Proof Sketch: To see that NE is true in every interpretation, pick an arbitrary interpretation **I**. Note that it suffices to show that the open modal formula '$\Box\exists y(y = x)$' is true$_{\mathbf{I}}$ at $\mathbf{w}_0$ (for by the definition of truth, this open formula will have be true with respect to every assignment function **f**; but if so, then '$\forall x\Box\exists y(y = x)$' will be true). To do that, we have to show that '$\exists y(y = x)$' is true$_{\mathbf{I}}$ at every possible world. So pick an arbitrary possible world, say $\mathbf{w}_1$. We have to show that '$\exists y(y = x)$' is true$_{\mathbf{I}}$ at $\mathbf{w}_1$, i.e., that for every assignment to the variables **f**, '$\exists y(y = x)$' is true$_{\mathbf{I},\mathbf{f}}$ at $\mathbf{w}_1$. So, we show, for an arbitrarily chosen assignment, say $\mathbf{f}_1$, that '$\exists y(y = x)$' is true$_{\mathbf{I},\mathbf{f}_1}$ at $\mathbf{w}_1$. Now call the individual which $\mathbf{f}_1$ assigns to the variable x '$\mathbf{i}_1$' (we know there must be such an individual since the domain is nonempty). Now to show '$\exists y(y = x)$' is true$_{\mathbf{I},\mathbf{f}_1}$ at $\mathbf{w}_1$, we have to show that there is some assignment function **f′** which differs from $\mathbf{f}_1$ at most in what it assigns to y and such that '$y = x$' is true$_{\mathbf{I},\mathbf{f}'}$ at $\mathbf{w}_1$. But consider the assignment function $\mathbf{f}^*_1$, which is just like $\mathbf{f}_1$ but which assigns $\mathbf{i}_1$ to the variable y (we know there must be such an assignment function, by the definition of an assignment function). Then, clearly, '$y = x$' is true$_{\mathbf{I},\mathbf{f}^*_1}$ at $\mathbf{w}_1$, since $\mathbf{f}^*_1(x) = \mathbf{f}^*_1(y)$ (and hence $\mathbf{d}_{\mathbf{I},\mathbf{f}^*_1}(x) = \mathbf{d}_{\mathbf{I},\mathbf{f}^*_1}(y)$).

The Converse Barcan Formula is Logically True

Proof: To see that the Converse Barcan Formula is true in every interpretation, pick an arbitrary interpretation **I**. To show that a conditional sentence is true$_{\mathbf{I}}$, the definition tells us that we must show that it is true$_{\mathbf{I}}$ at the actual world $\mathbf{w}_0$. To do this, we assume that the antecedent is true$_{\mathbf{I}}$ at $\mathbf{w}_0$ and then show that the consequent is true$_{\mathbf{I}}$ at $\mathbf{w}_0$. So assume that the antecedent of CBF, namely, $\Box\forall x\varphi$, is true$_{\mathbf{I}}$ at $\mathbf{w}_0$. It follows, by the definition of truth, that at every possible world $\mathbf{w}$, $\forall x\varphi$ is true$_{\mathbf{I}}$ at $\mathbf{w}$. It follows from this that at every possible world $\mathbf{w}$, every individual $\mathbf{i}$ in the domain satisfies$_{\mathbf{I}}$ φ at $\mathbf{w}$. [This conclusion takes a few liberties with the definition of satisfaction, but no harm comes from employing this simpler manner of speaking as if individuals satisfied formulas at worlds rather than strictly speaking in terms of assignment functions satisfying formulas at worlds.] Therefore, every individual $\mathbf{i}$ in the domain is such that for every world $\mathbf{w}$, $\mathbf{i}$ satisfies$_{\mathbf{I}}$ φ at $\mathbf{w}$. That is, every individual $\mathbf{i}$ satisfies$_{\mathbf{I}}$ $\Box\varphi$ at $\mathbf{w}_0$. So, $\forall x\Box\varphi$ is true$_{\mathbf{I}}$ at $\mathbf{w}_0$.

A Derivation of NE from SA and CBF

Consider any property P such that $\Box\forall z Pz$. P might be the property of *being self-identical*, for example. From this, CBF yields $\forall z\Box Pz$. But instantiate this to an arbitrary object, say x, to get $\Box Px$. Then we have the following instance of SA: $\Box(Px \rightarrow \exists y\, y = x)$. Thus, by the K axiom, it follows that $\Box\exists y\, y = x$, i.e., NE. Note that even in a language without identity, in which *existence* is expressed by a predicate '$E!$' and serious actualism is expressed by the formula $\Box[\varphi(x) \rightarrow E!x]$, we would still get the result that $\forall x\Box E!x$.

Prior's Modal Logic

One of the first philosophical logicians to think about these problems was Arthur Prior. He pointed out that SQML is "haunted by the myth that whatever exists exists necessarily" ([1968], p. 48). His goal was to develop a modal logic for contingent beings (see Prior [1957] and [1967]). Prior developed a solution to these problems by rejecting the interdefinability of the ‘necessity’ and ‘possibility’ operators and restricting the Rule of Necessitation. The central notion that underlies Prior's system is the notion of *necessary statability*. Prior's idea is that when *a* is a contingent being, then propositions about *a* are not even statable in a world where *a* doesn't exist; i.e., such propositions are not necessarily statable. Intuitively, only those formulas which are about necessary beings or which are wholly general in character are necessarily statable. Thus, Prior introduces the modal claim $S\varphi$ to indicate that the proposition denoted by φ is necessarily statable.

Prior then undermines the interdefinability of possibility and necessity by distinguishing ‘not possibly false’ from ‘necessarily true’ as follows. Using the operator ‘$\Diamond$’ as primitive, Prior labels any statement φ for which there is no world where it is false as ‘not possibly false’ (i.e., $\neg\Diamond\neg\varphi$). For example, when *a* is a contingent being, the statement ‘$Pa \rightarrow Pa$’ is not possibly false, since there is no world in which the statement is false. However, since this statement will be neither true nor false (but rather unstatable) at worlds where *a* doesn't exist, it is not a ‘necessarily true’ statement in the full or strong sense of being true in every possible world. Prior defines this strong sense of necessity in his object language in terms of possibility and statability as follows: φ is necessarily true iff φ is necessarily statable and φ is not possibly false. In formal terms:

$$\Box\varphi \equiv S\varphi \,\&\, \neg\Diamond\neg\varphi$$

So, when *a* is a contingent being, ‘$Pa \rightarrow Pa$’ is not a necessary truth. But when ‘*a*’ denotes an object that necessarily exists, ‘$Pa \rightarrow Pa$’ will be necessarily true. Also, completely general sentences like ‘$\forall xPx \rightarrow \forall xPx$’ will be necessarily true.

Given this distinction between weak necessity (‘not possibly false’) and strong necessity, Prior must make sure that the Rule of Necessitation never allows us to infer the strong necessity of a theorem of logic that is only weakly necessary. Thus, for Prior, the Rule of Necessitation must be reformulated as follows:

Revised RN: If $\vdash\varphi$, then $\vdash(S\varphi \rightarrow \Box\varphi)$

Thus, after establishing that $Pa \rightarrow Pa$ is a theorem of logic, we cannot infer that $\Box(Pa \rightarrow Pa)$. However, we can infer that $\neg\Diamond\neg(Pa \rightarrow Pa)$, since Prior does accept the following rule of inference:

> If $\vdash \varphi$, then $\vdash \neg\Diamond\neg\varphi$

It is now easy to see that BF, NE, and CBF are no longer theorems of Prior's logic. The proof of BF relied both on the interdefinability of possibility and necessity as well as on the unrevised Rule of Necessitation. (Specifically, the interdefinability of possibility and necessity plays a role behind the scenes in the second line of the second subproof in the derivation of BF, and the Rule of Necessitation was used in line 2 in the third subproof and in line 2 of the final, assembled proof of BF.) The proof of NE is undermined since it relied on unrevised RN as well. (Specifically, Revised RN will not permit the inference on line 3 of the derivation of NE.) Finally, the proof of CBF cannot proceed in the usual way using Revised RN. (Specifically, we cannot appeal to Revised RN on line 2 of the derivation of CBF.)

Since BF, NE, and CBF are no longer theorems, one might think that Prior had succeeded in finding the correct modal logic for actualism. However, few actualists have adopted this logic. The interdefinability of possibility and necessity has seemed just too elegant to abandon---it seems to capture something deep about the logical relationships among our modal beliefs. Actualists are divided on the queston of Prior's restriction on RN---some see it as unnecessary while others accept some such weakening of RN. Probably the most awkward consequence of Prior's logic, however, is the fact that logical contradictions which aren't necessarily statable turn out to be weakly possible! Before we explain why this is so, note that when *a* is a contingent being, the claim $\exists y(y = a)$ is not possibly false --- it is true at any world where *a* exists, and is neither true nor false at worlds where *a* fails to exist. As Deutsch observes, "Yet surely there is a sense in which ‘Prior [*a*] exists’ might have been *false*; and there is no way to express this in Prior's system" ([1990], 92-93). Prior here would emphasize that this weak necessity of *a*'s existence doesn't contradict the fact that *a* is a contingent being, for the fact that *a* is contingent is properly expressed by the fact that neither $\exists y(y = a)$ nor its negation are necessarily true (since neither is necessarily statable). However, if that is what it is to say that a fact is contingent, then any literal contradiction mentioning *a* will be contingent! For example, the contradiction Pa & $\neg Pa$ is not necessarily true, nor is its negation, since neither is statable in a world where *a* doesn't exist. So this contradiction becomes a contingent claim. Indeed, if we suppose that $\neg\Box\neg\varphi$ (using Prior's defined sense of $\Box$) defines a weak sense in which φ is possibly true, it turns out that both the formulas $\neg\exists y(y = a)$ and the contradictory formula Pa & $\neg Pa$ are possibly true in exactly this sense. As I have put it elsewhere ([1991], 348), Prior's modal logic "cannot distinguish the expression of [*a*'s] contingency from the possibility of manifest repugnancies".

Plantinga's Definition of an Individual Essence

Essential Properties

A property *P* is *essential to* an individual *x* if and only if it is not possible that *x* exist and fail to exemplify *P*.

Individual Essences

A property *E* is an *individual essence of* an individual *x* if and only if (i) *E* is essential to *x* and (ii) necessarily, for all individuals *y*, *y* exemplifies *E* if and only if *y* = *x*. Hence, *E* is an individual essence, simpliciter, if and only if it is possible that there be an individual *x* such that *P* is an individual essence of *x*.

Note that, by the above definition, an individual could have several individual essences.

Problems with the Actualist Accounts

Problems for Individual Essences

Plantinga's account is not without its problems. We will raise three that have appeared in the literature. Plantinga has reasonable responses to the first two. The third seems to be the most problematic.

An Extravagant Ontology

The first, a perhaps least pressing, problem of Plantinga's account is its commitment to a rich universe of fine-grained properties, relations, states of affairs, etc. However, the epistemological problems of platonism in general notwithstanding, abstract entities are largely recognized as, if perhaps not indispensible, extremely useful theoretical constructs, and are ubiquitous in contemporary philosophy of language, logic, mathematics, and linguistics, and in artificial intelligence. Hence, Plantinga's project is in no deeper water in this regard than many other well-regarded projects. For all but the most stringent nominalists, then, the only objection can be that the ontology is too rich, too fine-grained. However, once abstract entities are admitted at all, such a charge will stick only if the entities in question are not doing any reasonable philosophical work, and that is not the case in Plantinga's account; for all its richness, the elements of its ontology and their nature seem quite carefully chosen to play their respective roles. Hence, the objection here seems to boil down simply to a difference of philosophical taste. And that is not a serious objection.

Uninterpretability of the Semantics

Plantinga and Jager purport to be providing a genuine semantics for quantified modal languages, an account of the meaning of modal assertions. There are two related, and more serious, objections to their project, however. (These objections are based in part upon Linsky and Zalta [1994].)

First, Plantinga's modal semantics does not square with our basic semantic intuitions. In particular, on Plantinga's semantics, names denote, and quantifiers range over, individual essences. Intuitively, however (and also according to the current dominant theories of reference), names do no such thing; names denote individuals: ‘Quine’ denotes Quine, not his individual essence. Indeed, in order to denote haecceities, we resort to grammatically more complex constructions like gerunds that contain names referring to individuals, e.g., ‘being Quine’. The term ‘Quine’ here must be taken to refer to Quine, not an individual essence, lest the term denote, not an individual essence of Quine, but an individual essence of an individual essence of Quine.

This last point illustrates the second and more difficult objection, namely, that *Plantinga's semantics provides no way of interpreting the basic definitions and principles of the semantics itself.* According to the semantics, quantifiers range over individual essences and atomic formulas express coexemplification. Yet the metalinguistic quantifiers in the definitions of ‘individual essence’ and ‘coexemplification’ must, on pain of circularity, be taken to range over individuals. Again, the crucial principle P4 of Plantinga's semantics says that, necessarily, every object has an individual essence. But clearly, the universal quantifier here cannot itself be interpreted as a quantifier over individual essences, lest P4 express only the trivial proposition that, in every world **w**, every individual essence that is exemplified in **w** is coexemplified with the property **having an individual essence**. So, while P4 is intended to guarantee that there are enough individual essences, intepreted according to Plantinga's own semantics P4 turns out to be true even if there are no individual essences at all.

There are moves that one can imagine Plantinga and Jager making in response to these difficulties. For instance, perhaps they could add a domain of actual individuals to the semantics to serve as the referents for names. Again, perhaps Plantinga intends the semantics not to capture the denotation relation but rather only the relation of *expressing* that he has argued holds between names and individual essences (cf. Plantinga [1974]). The point, however, is that, if the account of Plantinga and Jager is to be understood as a genuine semantic theory as they seem to purport, numerous difficulties must be addressed before the account can be considered viable. If their semantics is to be understood in some other way, its nature and purpose need significant clarification and, where appropriate, modification.

Conceptual Difficulties with Individual Essences

More pernicious difficulties surround the notion of an individual essence itself, and in particular the notion of a haecceity. To get at the chief problem, first, define a property or relation to be *logically simple* (*simple*, for short) if it is not itself a negation, conjunction, disjunction, quantification, modalization, etc. of any other properties or relations. (The idea here, of course, is that logically simple properties correspond to basic predicates in a language, and logically complex properties are analogous to complex sentences. It is a bit difficult in fact to find any uncontroversial examples of logically simple properties. Perhaps certain fundamental mental states like happiness or physical states like *being a quark* or *having mass* qualify. For purposes here, however, we needn't delve deeper.) Next, say that a property **P** is *general* if it is possible both that (i) something **x** exemplify **P** and that (ii) possibly, something **y** distinct from **x** exemplify **P**. Intuitively, then, a property is general if it can be exemplified by more than one thing, albeit perhaps only at different times or in different possible worlds. The notion of generality can be extended to relations in an obvious way.

Now, haecceities are either simple or they are not. Both options are problematic. Plantinga refers to haecceities by means of two types of gerunds: grammatically simple gerunds like ‘being Quine’, and grammatically more complex gerunds like ‘being identical with Quine’. Those of the former sort suggest that haecceities are logically simple, the latter that they are logically complex. We consider them in turn.

If haecceities are logically complex, the central question is: In what does this logical complexity consist?

An appealing and quite popular answer dating back to Russell is that logical complexity, at least in part, involves a certain type of metaphysical complexity: a logically complex property, proposition, or relation is literally *constituted* by less complex metaphysical parts. (See Frege [1980], p. 169.) So, for example, the property **being human and over 6 feet tall** is constituted by the properties **being human** and **being over 6 feet tall**. And, most relevantly, *singular* properties and relations like **being a student of Quine** that involve expressions for a relation and an individual are constituted by those very entities, in this case, in this case, the relation **being a student of** and *Quine himself*.

If this account is correct, then Quine is a literal metaphysical component of the haecceity **being identical with Quine**. If so, however, then it seems that haecceities are ontologically dependent on their instances; no haecceity exists uninstantiated. For Quine is the very component that distinguishes **being identical with Quine** from every other haecceity, and hence he appears to be essential to its identity. But if that is correct, then haecceities cannot play the role of *possibilia*, for possibilia are, in a certain sense, necessary beings. Though perhaps not *actual* in every world, nontheless, for the possibilist, necessarily, for every *possibile* **x** and every world **w**, *there is* such a thing as **x** at **w**. But if haecceities are ontologically dependent upon their instances, then there are no uninstantiated haecceities. In particular, then, there are no haecceities that could be instantiated by Aliens, since, by hypothesis, no actual individual is possibly an Alien. Hence, Plantinga's semantics for (1) do not work, as they depend upon the existence of an uninstantiated haecceity. Plantinga, of course, could (and, in fact, does) just resist the idea that Quine is a constituent of **being identical with Quine**. However, he identifies no other problems with this conception of logical complexity, and provides no alternative account. Hence, this response seems ad hoc.

A somewhat stronger move for Plantinga is to deny that haecceities are logically complex and take them instead to be logically simple, as suggested by grammatically simple gerunds like ‘being Quine’ that do not involve reference to identity or any other property or relation. Now, the fact that one still has to refer to Quine in order to refer to his haecceity might suggest that **being Quine** is no less ontologically dependent upon Quine than is **being identical with Quine**. The important difference in this case, however, is that there is no apparent logical complexity that needs explaining: **being Quine** -- or perhaps better, **quineity** -- as it happens, simply holds essentially and uniquely of Quine. True enough, we can only refer to Quine's haecceity by referring, at least obliquely, to Quine. However, all that follows from that is that if Quine hadn't existed, it would not have been possible to refer to his haecceity, at least, not by means of a gerund involving a proper name of Quine. The haecceity itself is, arguably, no more ontologically dependent upon Quine than is the number 2. Hence, there is no reason to deny that logically simple haecceities, like other logically simple properties, are necessary beings, and hence no reason to think that they cannot play all of the metaphysical roles demanded of them in Plantinga's account.

The chief objection to this move now, however, is whether Plantinga has distinguished his own view sufficiently from possibilism. On his account, haecceities are logically simple but non-general properties. But this seems a very odd combination. Intuitively, at first blush anyway, properties and relations are common, general, repeatable characteristics of, or connections between, things -- redness, wisdom, humanity, marriage, adjacency, etc. Recognition of shareability among many particulars, awareness of a

one over many, is what gave rise to the concept of a property in the first place. In fact, of course, not all properties are general. But, intuitively again, non-generality comes about by virtue of logical complexity, by virtue of the manner in which the components of a complex property are "woven together" logically, e.g., **being smaller than every other prime number**, **possibly being the father of Xantippe**, or **being identical with Quine**. Hence, it follows from these intuitions that, necessarily, all logically simple properties are general. However, Plantinga flouts these intuitions in order to introduce an entirely new class of simple property whose sole function is to serve as an actualist counterpart to *possibilia*. But given their oddity, it is far from clear that there is any greater philosophical virtue in postulating logically simple but essentially non-general properties than in postulating that there are objects that are not actual. So whatever victory Plantinga can claim for actualism here seems Pyrrhic at best. (Some readers may be interested in the supplementary document Qualitative Essences and a Final Defense for Plantinga.)

Return to Actualism

Problems for World Stories

Though promising and intuitive, Adams' account, like Plantinga's, suffers from some serious objections.

Loss of Compositionality

One of the traditional strengths of possible worlds semantics is that it provides a compositional semantics for modal notions. A virtue of the Plantinga/Jager approach is that it preserves compositionality. Haecceities, however, are the key to their approach. Adams' account by contrast, with its rejection of haecceities, sacrifices compositionality. Notably, the semantics of (1) must stop at (14): Because there are in fact no Aliens, the proposition **There are Aliens** has no witnesses, no objects that, by virtue of their actual or possible properties, make it true. Hence, unlike compositional accounts, one cannot further analyze the right side of the biconditional in (14).

The Iterated Modalities Objection

However, perhaps the sacrifice of compositionality is not too high a price for the strong actualist to pay. After all, we *understand* quantification well enough from standard, nonmodal Tarskian semantics. And given strong actualism, it is no surprise that (14) should be unanalyzable, for there *are* no possible Aliens to serve as witnesses to (14). The real goal of a semantics of modality is to provide an analysis of our ordinary use of *modal* operators, not extensional ones like quantification. From that perspective, the unanalyzability of (14) is unproblematic, as the important work has been done in analyzing the modal operator in (1).

However, at this point Adams falls victim to the iterated modalities objection. Recall the following proposition:

(7) The pope could have had a son who could have become a priest

that is, formally,

(9) $\Diamond\exists x(Sxp \;\&\; \Diamond Px)$.

On Adams' semantics, (9) is true if and only if

(15) '$\exists x(Sxp \;\&\; \Diamond Px)$' (i.e., the proposition **Wojtyla has a son who could have become a priest**) is true at some world **w**.

The problem now is that, if we stop the analysis of (9) with (15), the semantic prize noted above -- the analysis of our ordinary modal locutions in terms of possible worlds -- is lost, as (15) contains an embedded modal operator that cannot be analyzed in terms of world stories. For to do so, unlike the case of (14), one must produce a witness for '$\exists x(Sxp \;\&\; \Diamond Px)$' about whom it is true at some world that *he* is a priest. That is, in order to analyze the embedded modal operator, (15) seems to require analysis along the following lines:

(16) For some some individual *x*, '$Sxp \;\&\; \Diamond Px$' (i.e., the proposition ***x* is a son of Wojtyla and *x* could have become a priest**) is true at some world **w**,

which then enables us to analyze the embedded modal operator:

(17) For some some individual *x*, '*Sxp*' (i.e., the proposition ***x* is a son of Wojtyla**) is true at some possible world **w** and, for some possible world **u**, '*Px*' (i.e., the proposition ***x* is a priest**) is true at **u**.

But by strong actualism, there is no such instance *x*, as the pope has no children and, assuming that one's actual parents are necessarily one's parents (provided one exists), nothing actual could have been the pope's child. Hence, given strong actualism, there is no information about any such *x*, no singular proposition that is directly about any such *x*. Hence, there is no proposition of the requisite form ***x* is a son of Wojtyla** specified in (17) to be true at some possible world, that is, to be a member of some world story. Granted, there *could* be such a proposition, but, given strong actualism, there isn't in fact. Hence, Adams' semantics fails to provide the analysis of our ordinary modal discourse that it purports to provide.

Return to Actualism

Problems for World Propositions

Fine's account leaves us with a general question: What role, then, are possible worlds playing in accounts like Plantinga's, Adams', and Fine's in which possible worlds are defined in terms of a primitive modality? If these accounts are not providing a semantical *analyses* of modality, what is their purpose? Why clutter our ontology with them if they do not lead to any genuine semantical insight?

A natural answer is that, even if worlds don't provide us with a semantical *analysis* of modality, possible worlds are still tremendously useful in the formal analysis of modality. Notably, the apparatus of possible world semantics enables us to define such critical properties as consistency and completeness for formal systems of modality. It also enables a definition of the critical notion of logical consequence for modal languages. However, the formal, mathematical *apparatus* of possible world semantics -- the name notwithstanding -- is completely independent of any philosophical conception of possible worlds. There need be no "intended" possible worlds model -- one actually containing possible worlds of some ilk -- in order for us to employ the apparatus to define and use the notions above. Hence, the usefulness of the formal semantics provides us with no reason to allow possible worlds into our ontology.

However, perhaps that is too hasty. For while it is true that possible world semantics is independent of the question of whether there are any possible worlds, by the same token, if there are no possible worlds in any sense, it is difficult to justify the use of possible worlds models as a reasonable formal mechanism for studying the semantical properties of modal languages. For if modal truth is not related in any way to truth in honest-to-goodness possible worlds, then it is hard to see any connection between the informal, intuitive notions modal truth and entailment and the formal notions of truth-in-a-(possible-worlds)-model and logical consequence. Arguably, then, even if they do not provide semantical analyses, possible worlds play an essential role in linking our formal possible world semantics to our ordinary modal concepts of truth and logical consequence. And this could be seen as a motivation for accounts like Adams', Plantinga's, and Fine's. The possible worlds of these accounts give substance to the important intuition that *there are* other ways that things could have been, that there is indeed an intuitive connection between modal truth and quantification over in possible worlds. Thus, the "worlds" in a formal possible worlds model can be viewed as something more than mere formal artifacts. They can be seen as actual representations of other ways the world could have been, and quantification over them as a reasonable representation of an important way in which we think intuitively about modal truth. This connection between the "worlds" of a formal model and genuine possible worlds thus establishes a connection between truth-in-a-model and honest-to-goodness modal truth. (Although without the actual existence of an *intended* model, as is the case for Adams and Fine, rather more would need to be said to flesh out the nature of this connection.) Hence, even though they do not provide semantical analyses, the accounts in question can, at least, be thought of as providing a philosophical justification for considering the apparatus of formal possible worlds models to be a reasonable formal mechanism for studying the semantical properties of modal languages. An actualist account that attempts to do without worlds but which retains an understanding of possible world semantics that ties it to our ordinary notion of modal truth is discussed in the section Dispensing With Worlds.

Return to Actualism

Problems for Roles

McMichael's semantics seems reasonably successful in coping with the problems facing the semantics of Plantinga and Adams. The account is actualist, but neither requires haecceities nor falls prey to the compositionality and iterated modalities objections. However, the success of the account comes at a fairly steep intuitive price, as it abandons strong intuitions about *de re* modality. McMichael would have us understand (21), the statement that Socrates could have been foolish, to be expressing a fact about a complex, abstract property, a role, that bears some sort of accessibility relation to another role that is exemplified by Socrates. actual role of Socrates. Similarly, (9) expresses a fact about a role accessible to the Pope's actual role. But one still wonders: what do such facts about roles and their accessibility to one another have to do with the properties *Socrates* could have had? What, in particular, is the connection between the accessibility of one role to another and the modal properties of individuals? What we'd like to say is that a role **S** is accessible to, say, Socrates' actual role $\mathbf{R_s}$ just in case it is a role Socrates could have exemplified. But, in McMichael's semantics, to say that Socrates could have exemplified any given property **P** (a role in particular) is only to say that some role that includes **P** is accessible to $\mathbf{R_s}$, and we are back where we started with no insight into the connection between accessibility and the modal properties of Socrates. On this score, both possibilism and haecceitism account far more satisfactorily for our modal intuitions.

Return to Actualism

Problems for the No-world Account

Perhaps the central problem for the no-world account is that is abandons traditional ideas about truth and modality. The no-worlder counts his eschewal of worlds as a virtue. However, as Linsky and Zalta [1996] note, this is problematic for several reasons. For if we abandon possible worlds, we must also abandon the "seminal insight" that necessary truth is truth in all possible worlds. And this is problematic for several reasons, for it not only undermines the elegant, extensional characterization of the truth conditions of modal claims, but also dismisses the intuition so strongly evident in ordinary thinking about modality that there exist alternative *ways the world might have been*. For the no-worlder, however, there are no worlds, and hence no intended model whose indices are genuine possible worlds. There are instead only purely formal intended* models that possibly model the structure of modal reality. But, Linsky and Zalta ask,

> ... surely there is something more to modal truth than this; surely *necessity* and *possibility* are about something besides the structure of intended* models, something which *grounds* modal truth and which is modeled by an intended model. ([1994], 444)

But intended* models are not really *models* of any*thing*. At best the have the property of being actual objects that *possibly* model the *structure* of modal reality. But a model of the pure structure of modal reality, the objection might continue, is not the same as a genuine model of modal reality. On the no-

worlds approach,

> ...we cannot say that modal discourse is in part *about* the objects over which the quantifiers range, at least not in the same way that we can say that nonmodal language is about these objects. (Linsky and Zalta, [1994], 444)

And if not, it is hard to see in what sense the no-worlds approach accounts for modal truth at all.

Return to Actualism

Problems for New Actualism

New actualism is a powerful and elegant solution to the problem of possibilism. It appears to have all the theoretical power of possibilism without possibilism's commitment to mere possibilia; everything there is is actual. However, one might argue that it is no surprise that new actualism retains the theoretical power of possibilism, because new actualism is nothing more than thinly veiled possibilism: the new actualist's "actuality" is just the possibilist's being, and contingent nonconcreteness is nothing but the possibilist's mere possibility; nothing but terminology distinguishes a mere *possibile* from a possibly (but not actually) concrete individual.

Even if this is all there were to new actualism, it would not be insignificant. For, in that case, new actualism shows that the standard definition of actualism has not gotten to the heart of the matter -- that actualism is not best characterized as the thesis that everything there *is*, in any sense, is actual. For new actualism demonstrates, at least, that there is a way of systematically reclothing possibilist statements in actualist guise.

This might prompt the "classical" actualist to try to get at the essence of her view in a slightly different way. The real target of the claim that everything is actual is the possibilist's division of being into two modes: actuality and mere possibility (i.e., contingent nonactuality). The new actualist certainly denies *that* division; there are indeed no mere *possibilia* for the new actualist, no objects that are, but which fail to be actual. However, the classical actualist would argue that the new actualist still violates the spirit of actualism. The new actualist does indeed maintain a single sense of being; but in place of the possibilist's division of being into two modes -- actuality and contingent nonactuality -- the new actualist substitutes a division of actuality into two modes: concreteness and contingent nonconcreteness. It is difficult not to see this as a mere relabeling of the possibilist's distinction. Most classical actualists will, therefore, regard new actualism as having the *form* of actualism without having the content necessary to serve as a genuine solution to the possibilist challenge.

For further debate on new actualism see Tomberlin [1996] and the reply by Zalta and Linsky [1996].

Qualitative Essences and a Final Defense for Plantinga

There is one final possibility that Plantinga could pursue. On the assumption that all logically simple properties are general, say that a property (or proposition) is *purely qualitative* if it is either logically simple or logically complex but "constructed" from purely qualitative properties, relations, and propositions, that is, if it is the conjunction, negation, modalization, quantification, etc of purely qualitative properties, relations, and propositions. For example, **being smaller than every other prime number** is a conjunction of the properties **being a prime number** and the quantified property (expressed somewhat awkwardly) **being something smaller than every prime number distinct from it** -- in the notation of the lambda calculus: $[\lambda x\ \ (Px\ \&\ \forall y((Py\ \&\ x \neq y) \rightarrow Sxy))]$. Again, **being the father of something** is the existential generalization of one of the "argument places" of the **father of** relation. By contrast, properties that "involve" a particular individual like **being Quine** and **being married to Xantippe** are not purely qualitative, as they involve the individuals Quine and Xantippe.

Now, there surely are some purely qualitative individual essences, e.g., **being smaller than every other prime number**. However, the only clear examples of such belong to necessary beings like the number 2. The real question is whether *contingent* beings have purely qualitative essences. Adams [1979] has argued convincingly that they do not. His central argument is that, given any possible world **w**, there is a world Sym(**w**) that is "symmetrical" with respect to **w**. The idea of symmetry here is difficult to define precisely, but the intuitive idea is that Sym(**w**) contains two parts, each of which is a sort of "copy" of **w**. One of these copies --- call it **C1** -- is (but for properties arising from the existence of the other copy) identical to **w** in both qualititative and nonqualitative respects, and in particular *contains exactly the same objects*as **w**. The other copy --- call it **C2** --- is an exact *qualitative replica* of **w**, i.e., a copy that is indistinguishable from **w** in all qualitative respects (other than those arising from the existence of **C1**). Every object in **C1**, and hence in **w** thus has a qualitative "doppelgänger" in **C2**, an exact replica that has all of its purely qualitative properties. Given this, it seems that there is a possible world **w′** such that Sym(**w′**) = Sym(**w**), but where now **w′** is identical with **C2**, and where **C1** is the replica. It follows that, for every possible world **w**, there is another world **w′** that is qualitatively identical with **w**, but which contains only doppelgängers of the objects in **w**.

Now, one might argue that all that follows from the example is that, for any object *x* and any world **w** containing *x*, there is a distinct object *y* in some other world **w′** that has all of *x*'s qualitative *nonmodal* properties in **w**. That is, Adams' argument from symmetrical worlds only makes plausible the idea that, necessarily, every object *x* has, as one might say, a *de facto* doppelgänger, something qualitatively identical to it with regard to the properties it just happens to exemplify. It does not follow that,

necessarily, there is a *complete*, or *modal* doppelgänger *y* of *x*, i.e., that, for any world **w** in which *x* exists, there is a *de facto* doppelgänger of *x* with respect to **w** such that, in every other world $\mathbf{w}'$ in which *x* exists, there is a world $\mathbf{w}''$ such that *y* is a *de facto* doppelgänger in $\mathbf{w}''$ of *x* with respect to $\mathbf{w}'$, and furthermore, that *x* is a modal doppelgänger of *y*. Hence it does not follow that there are no purely qualitative essences -- perhaps the purely qualitative *modal* properties of *x* are sufficient to distinguish it from any of its *de facto* doppelgängers, i.e., that none of its *de facto* doppelgängers are modal doppelgängers.

This is certainly a line worth pursuing. However, the central problem with it is that there appears to be no intuitive justification for this claim. Given that a doppelgänger *y* in $\mathbf{w}'$ is qualititatively identical to *x* with respect to the nonmodal properties *x* exemplifies in **w**, what possible ground could there be for asserting that the same couldn't to true of *y* with respect to any world in which *x* exists? Intuitively, it seems, there are no such grounds. A defender of this line would have to provide some.

Why NE and CBF Are Harmless Consequences of SQML

To see in more detail why the Necessary Existence theorem (NE) of SQML is a harmless consequence of SQML, note that, according to new actualism, Socrates does exist necessarily, but since he is not necessarily concrete, NE does not imply that Socrates is a "necessary being". As we saw above, Socrates' contingency lies in the fact that he is concrete at some possible worlds and nonconcrete at others. Necessary beings, by contrast, are objects that are either concrete at every possible world (like Spinoza's God) or nonconcrete at every possible world (like numbers, sets, etc.). This means that the "contingently nonconcrete" are aptly named, since they are not necessary beings in either of these senses. So the claim that "Everything necessarily exists" (NE), does not conflict with our intuition that some beings are contingent, once the notion of what it is to be contingent is properly understood. Nor does its necessitation NNE. So if NE and NNE are acceptable consequences of SQML, the worry about the Converse Barcan Formula (CBF) disappears as well, for the fact that it, together with Serious Actualism (SA), implies NE, is of little consequence.

New Actualism and Iterated Modalities

To see that iterated modalities pose no problem for new actualism, recall first that the sentences

(7) The pope (i.e., Karol Wojtyla) could have had a son who could have become a priest.
(8) There could be a planet disturbing the orbit of planet Y and it could have a period of Z years.

can be represented as follows:

(9) $\Diamond \exists x(Sxp \;\&\; \Diamond Px)$
(10) $\Diamond \exists x(Dxy \;\&\; \Diamond Pxz)$

These have straightforward actualist truth conditions requiring no possibilia. For consider (9). The thing *x* which might have been both the pope's son and possibly a priest is a contingently nonconcrete object that at some other world is the pope's son and at yet another world is a priest.

Classical Logic

Typically, a *logic* consists of a formal or informal language together with a deductive system and/or a model-theoretic semantics. The language is, or corresponds to, a part of a natural language like English or Greek. The deductive system is to capture, codify, or simply record which *inferences* are correct for the given language, and the semantics is to capture, codify, or record the meanings, or truth-conditions, or possible truth conditions, for at least part of the language.

The following sections provide the basics of a typical logic, sometimes called "classical elementary logic" or "classical first-order logic". Section 2 develops a formal language, with a rigorous syntax and grammar. The formal language is a recursively defined collection of strings on a fixed alphabet. As such, it has no meaning, or perhaps better, the meaning of the formulas is given by the deductive system and the semantics. Some of the symbols have counterparts in ordinary language. We define an *argument* to be a non-empty collection of formulas in the formal language, one of which is designated to be the conclusion. The other formulas (if any) in an argument are its premises. Section 3 sets up a deductive system for the language, in the spirit of natural deduction. An argument is *derivable* is there is a deduction from some of its premises to its conclusion. Section 4 provides a model-theoretic semantics. An argument is *valid* if there is no interpretation (in the semantics) in which its premises are all true and its conclusion false. This reflects the longstanding view that a valid argument is truth-preserving.

In Section 5, we turn to relationships between the deductive system and the semantics, and in particular, the relationship between derivability and validity. We show that an argument is derivable only if it is valid. This pleasant feature, called *soundness*, entails that no deduction takes one from true premises to a false conclusion. Thus, deductions preserve truth, and there aren't too many deductions. Then we establish a converse, called *completeness*, that an argument is valid only if it is derivable. This establishes that the deductive system is rich enough to provide a deduction for every valid argument. There are enough deductions. All and only valid arguments are derivable. We briefly indicate other features of the logic, some of which are corollaries to soundness and completeness.

---

1. Introduction

Today, logic is both a branch of mathematics and a branch of philosophy. In most large universities, both departments offer sequences of courses in logic, and there is usually a lot of overlap between them. Formal languages, deductive systems, and model-theoretic semantics are mathematical objects and, as such, the logician is interested in their mathematical properties and relations. Soundness, completeness, and most of the other results reported below are typical examples. Philosophically, logic is the study of *correct reasoning*. Reasoning is an epistemic, mental activity. This raises questions concerning the philosophical relevance of the mathematical aspects of logic. How do deducibility and validity, as properties of formal languages--sets of strings on a fixed alphabet--relate to correct reasoning? What do the mathematical results reported below have to do with the original philosophical issue? This is an instance of the philosophical problem of explaining how mathematics applies to non-mathematical reality.

Typically, ordinary reasoning takes place in a natural language, or perhaps a natural language augmented with some mathematical symbols. So our question begins with the relationship between a natural language and a formal language. Without attempting to be comprehensive, it may help to sketch several options on this matter.

One view is that the formal languages accurately exhibit actual features of certain fragments of a natural language. Some philosophers claim that declarative sentences of natural language have underlying *logical forms* and that these forms are displayed by formulas of a formal language. Other writers hold that (successful) declarative sentences express *propositions*; and formulas of formal languages somehow display the forms of these propositions. On views like this, the components of a logic provide the underlying deep structure of correct reasoning. A chunk of reasoning in natural language is correct if the forms underlying the sentences constitute a valid or deducible argument. See for example, Montague [1974], Davidson [1984], Lycan [1984].

Another view, held at least in part by Gottlob Frege and Wilhelm Leibniz, is that because natural languages are vague and ambiguous, they should be *replaced* by formal languages. A similar view, held by W. V. O. Quine (e.g., [1960], [1986]), is that a natural language should be *regimented*, cleaned up for serious scientific and metaphysical work. One desideratum of the enterprise is that the logical structures in the regimented language should be transparent. It should be easy to "read off" the logical properties of each sentence. A regimented language is similar to a formal language regarding, for example, the explicitly presented rigor of its syntax and its truth conditions.

On a view like this, deducibility and validity represent *idealizations* of correct reasoning in natural language. A chunk of reasoning is correct to the extent that it corresponds to, or can be regimented by, a valid or deducible argument in a formal language.

When mathematicians and many philosophers reason, they occasionally invoke formulas in a formal language to help disambiguate, or otherwise clarify what they mean. In other words, sometimes formulas in a formal language are *used* in ordinary reasoning. This suggests that one might think of a formal language as an *addendum* to a natural language. Then our present question concerns the relationship between this addendum and the original language. What do deducibility and validity, as sharply defined on the addendum, tell us about correct reasoning in general?

Another view is that a formal language is a *mathematical model* of a natural language in roughly the same sense as, say, a collection of point masses is a model of a system of physical objects, and the Bohr construction is a model of an atom. In other words, a formal language displays certain features of natural languages, or idealizations thereof, while ignoring or simplifying other features. The purpose of mathematical models is to shed light on what they are models of, without claiming that the model is accurate in all respects or that the model should replace what it is a model of. On a view like this, deducibility and validity represent mathematical models of (perhaps different aspects of) correct reasoning in natural languages. Correct chunks of reasoning correspond, more or less, to valid or deducible arguments; incorrect chunks of reasoning roughly correspond to invalid or non-deducible arguments. See, for example, Corcoran [1973] or Shapiro [1998].

There is no need to adjudicate this matter here. Perhaps the truth lies in a combination of the above options, or maybe some other option is the correct, or most illuminating one. I raise the matter only to lend some philosophical perspective to the formal treatment that follows.

2. Language

Here we develop the basics of a formal language, or to be precise, a class of formal languages. Again, a formal language is a recursively defined set of strings on a fixed alphabet. Some aspects of the formal languages correspond to, or have counterparts in, natural languages like English. Technically, this "counterpart relation" is not part of the formal development, but I will mention it from time to time, to motivate some of the features and results.

Building blocks

We begin with analogues of *singular terms,* linguistic items whose function is to denote a person or object. We call these *terms*. We assume a stock of *individual constants*. These are lower-case letters, near the beginning of the Roman alphabet, with or without numerical subscripts:

$a, a_1, b_{23}, c, d_{22}$, etc.

We envisage a potential infinity of individual constants. In the present system each constant is a single character, and so individual constants do not have an internal syntax. Thus we have an infinite alphabet. This last could be avoided by taking a constant like d_{22}, for example, to consist of three characters, a lowercase "*d*" followed by a pair of subscript "2"s.

We also assume a stock of *individual variables*. These are lower-case letters, near the end of the alphabet, with out without numerical subscripts:

w, x, y_{12}, z, z_4, etc.

Variables serve a dual function. Sometimes a variable is used as a singular term to denote a specific, but unspecified (or arbitrary) object. For example, a mathematician might start a derivation: "Let x be a natural number". Variables are also used to express generality, as in the mathematical assertion that for any natural number x, there is a natural number y, such that $y>x$ and y is prime. Some logicians employ different symbols for unspecified objects (sometimes called "individual parameters") and variables used to express generality.

Constants and variables are the only terms in our formal language, so all of our terms are simple, corresponding to proper names and pronouns. Some authors also introduce *function letters*, which allow complex terms corresponding to: "7+4" and "the wife of Bill Clinton", or complex terms containing variables, like "the father of x" and "x/y". Logic books aimed at mathematicians are likely to contain function letters, probably due to the centrality of functions to mathematical discourse. Books aimed at a more general audience (or at philosophy students), may leave out function letters, since it simplifies the syntax and theory. We follow the latter route here. This is an instance of a general tradeoff between presenting a system with greater expressive resources, at the cost of making its formal treatment more complex.

For each natural number n, we introduce a stock of n-place *predicate letters*. These are upper-case letters at the beginning or middle of the alphabet. A superscript indicates the number of places, and there may or may not be a subscript. For example,

A^3, $B^3{}_2$, P^3, etc.

are three-place predicate letters. We often omit the superscript, when no confusion will result. We also add a special two-place symbol "=" for identity.

Zero-place predicate letters are sometimes called "sentence letters". They correspond to free-standing sentences whose internal structure does not matter. One-place predicate letters, called "monadic predicate letters", correspond to linguistic items denoting properties, like "being a man", "being red", or "being a prime number". Two-place predicate letters, "binary predicate letters", correspond to linguistic items denoting binary relations, like "is a parent of" or "is greater than". Three-place predicate letters

correspond to three-place relations, like "lies on a straight line between". And so on.

The *non-logical terminology* of the language consists of its individual constants and predicate letters. The symbol "=", for identity, is not a non-logical symbol. In taking identity to be logical, we provide explicit treatment for it in the deductive system and the model-theoretic semantics. Most authors do the same, but there is some controversy over the issue (Quine [1986, Chapter 5]). If K is a set of constants and predicate letters, then we give the fundamentals of a language $\mathcal{L}1K=$ built on this set of non-logical terminology. It may be called the *first-order language with identity* on K. A similar language that lacks the symbol for identity (or which takes identity to be non-logical) may be called $\mathcal{L}1K$, first-order logic without identity.

Atomic formulas

If V is an n-place predicate letter in K, and $t_1, ..., t_n$ are terms of K (i.e., constants in K or variables), then $Vt_1... t_n$ is an *atomic formula* of $\mathcal{L}1K=$. Notice that the terms $t_1, ..., t_n$ need not be distinct. Examples of atomic formulas include:

P^4xaab, C^1x, C^1a, D^0, A^3abc.

The last one is an analogue of a statement that a certain relation (A) holds between three objects (a, b, c). If t_1 and t_2 are terms, then $t_1=t_2$ is an atomic formula of $\mathcal{L}1K=$. It corresponds to an assertion that t_1 is identical to t_2.

If an atomic formula has no variables, then it is called an *atomic sentence*. If it does have variables, it is called an *open formula*. In the above list of examples, the first and second are open; the rest are sentences.

Compound formulas

We now introduce the final items of the lexicon:

$\neg$, &, $\vee$, $\rightarrow$, $\forall$, $\exists$, (,)

We give a recursive definition of a *formula* of $\mathcal{L}1K=$:

1. All atomic formulas of $\mathcal{L}1K=$ are formulas of $\mathcal{L}1K=$.

2. If θ is a formula of $\mathcal{L}1K=$, then so is $\neg\theta$.

Asserting a sentence corresponding to $\neg\theta$ is tantamount to denying the sentence corresponding to θ. The symbol "$\neg$" is called "negation", and is a unary connective.

3. If θ and ψ are formulas of $\mathcal{L}1K$=, then so is $(\theta \,\&\, \psi)$.

The ampersand "&" corresponds to the English "and" (when "and" is used to connect sentences). So $(\theta \,\&\, \psi)$ can be read "θ and ψ". The formula $(\theta \,\&\, \psi)$ is called the "conjunction"of θ and ψ.

4. If θ and ψ are formulas of $\mathcal{L}1K$=, then so is $(\theta \vee \psi)$.

The wedge "$\vee$" corresponds to "either . . . or . . . or both", so $(\theta \vee \psi)$ can be read "θ or ψ". The formula $(\theta \,\&\, \psi)$ is called the "disjunction"of $\theta$and ψ.

5. If θ and ψ are formulas of $\mathcal{L}1K$=, then so is $(\theta \rightarrow \psi)$.

The arrow "$\rightarrow$" corresponds to "if . . . then . . . ", so $(\theta \rightarrow \psi)$ can be read "if θ then ψ" or "θ only if ψ".

The symbols "&", "$\vee$", and "$\rightarrow$" are called "binary connectives", since they serve to "connect" two sentences into one. Some authors introduce $(\theta \leftrightarrow \psi)$ as an abbreviation of $((\theta \rightarrow \psi) \,\&\, (\psi \rightarrow \theta))$. The symbol "$\leftrightarrow$" is an analogue of the locution "if and only if".

6. If θ is a formula of $\mathcal{L}1K$= and *v* is a variable, then $\forall v\, \theta$ is a formula of $\mathcal{L}1K$=.

The symbol "$\forall$" is called a *universal quantifier*, and is an analogue of "for all"; so $\forall v\theta$ can be read "for all *v*, θ".

7. If θ is a formula of $\mathcal{L}1K$= and *v* is a variable, then $\exists v\, \theta$ is a formula of $\mathcal{L}1K$=.

The symbol "$\exists$" is called an *existential quantifier*, and is an analogue of "there exists" or "there is"; so $\exists v\, \theta$ can be read "there is a *v* such that θ".

8. That's all folks. That is, all formulas are constructed in accordance with rules (1)-(7).

Clause (8) allows us to do inductions on the complexity of formulas. If a certain property holds of the atomic formulas and is closed under the operations presented in clauses (2)-(7), then the property holds of all formulas.

We next define the notion of an occurrence of a variable being *free* or *bound* in a formula. All variables that occur in an atomic formula are free. If a variable occurs free (or bound) in θ or in ψ, then that same occurrence is free (or bound) in $\neg\theta$, $(\theta \,\&\, \psi)$, $(\theta \vee \psi)$, and $(\theta \rightarrow \psi)$. That is, the (unary and binary) connectives do not change the status of variables that occur in them. All occurrences of the variable *v* in

θ are bound in $\forall v\,\theta$ and $\exists v\,\theta$. Any *free* occurrences of *v* in θ are bound by the initial quantifier. All other variables that occur in θ are free or bound in $\forall v\,\theta$ and $\exists v\,\theta$, as they are in θ. A variable that immediately follows a quantifier (as in "$\forall x$" and "$\exists y$") is neither free nor bound. We do not think of those as occurrences of the variable.

For example, in the formula ($\forall x(Axy \vee Bx)$ & Bx), the occurrences of "*x*" in *Axy* and in the first *Bx* are bound by the quantifier. The occurrence of "*y*" and last occurrence of "*x*" are free. In $\forall x(Ax \rightarrow \exists xBx)$, the "*x*" in *Ax* is bound by the initial universal quantifier, while the other occurrence of *x* is bound by the existential quantifier. The above syntax allows this "overlap" of bound variables, and it does not create an ambiguity, but we will avoid such formulas, as a matter of taste and clarity

Free variables correspond to place-holders, while bound variables are used to express generality. If a formula has no free variables, then it is called a *sentence*. If a formula has free variables, it is called *open*.

Features of the syntax

Before turning to the deductive system and semantics, I mention a few features of the language, as developed so far. This helps draw the contrast between formal languages and natural languages like English.

We assume at the outset that all of the categories are disjoint. For example, no connective is also a quantifier or a variable, and the non-logical terms are not also parentheses or connectives. Also, the items within each category are distinct. For example, the sign for disjunction does not do double-duty as the negation symbol, and perhaps more significantly, no two-place predicate is also a one-place predicate.

> **Theorem 1**. Every formula of $\mathcal{L}1K$= has the same number of left and right parentheses. Moreover, each left parenthesis corresponds to a unique right parenthesis, which occurs to the right of the left parenthesis. Similarly, each right parenthesis corresponds to a unique left parenthesis, which occurs to the left of the given right parenthesis. If a parenthesis occurs between a matched pair of parentheses, then its mate also occurs within that matched pair. In other words, parentheses that occur within a matched pair are themselves matched.
>
> **Proof**: By clause (8), every formula is built up from the atomic formulas using clauses (2)-(7). The atomic formulas have no parentheses (by the policy that the categories are disjoint). Parentheses are introduced only in clauses (3)-(5), and each time they are introduced as a matched set. So at any stage in the construction of a formula, the parentheses are paired off.

One difference between natural languages like English and formal languages like $\mathcal{L}1K$= is that the latter are not supposed to have any ambiguities. Our policy that the different categories of symbols do not overlap, and that no symbol does double-duty helps avoid the kind of ambiguity, sometimes called

"equivocation", that occurs when a single word has two meanings: "I'll meet you at the bank." But there are other kinds of ambiguity. Consider the English sentence:

> John is married, and Mary is single, or Joe is crazy.

It can mean that John is married and either Mary is single or Joe is crazy, or else it can mean that either both John is married and Mary is single, or else Joe is crazy. An ambiguity like this, due to different ways to parse the same sentence, is sometimes called an "amphiboly". If our formal language did not have the parentheses in it, it would have amphibolies. For example, there would be a "formula" $A \& B \vee C$. Is this supposed to be $((A \& B) \vee C)$, or is it $(A \& (B \vee C))$? The parentheses resolve what would be an amphiboly.

Can we be sure that there are no other amphibolies in our language? That is, can we be sure that each formula of $\mathcal{L}1K$= can be put together in only one way? Showing this is our next task.

Let us temporarily use the term "unary marker" for the negation symbol (¬) or a quantifier followed by a variable (e.g., $\forall x$, $\exists z$).

> **Lemma 2**. Each formula consists of a string of zero or more unary markers followed by either an atomic formula or a formula produced using a binary connective, via one of clauses (3)-(5).
>
> **Proof**: We proceed by induction on the complexity of the formula or, in other words, on the number of formation rules that are applied. The Lemma clearly holds for atomic formulas. Let n be a natural number, and suppose that the Lemma holds for any formula constructed from n or fewer instances of clauses (2)-(7). Let θ be a formula constructed from n+1 instances. The Lemma holds if the last clause used to construct θ was either (3), (4), or (5). If the last clause used to construct θ was (2), then θ is $\neg\psi$. Since ψ was constructed with n instances of the rule, the Lemma holds for ψ (by the induction hypothesis), and so it holds for θ. Similar reasoning shows the Lemma to hold for θ if the last clause was (6) or (7). By clause (8), this exhausts the cases, and so the Lemma holds for θ, by induction.
>
> **Lemma 3**. If a formula θ contains a left parenthesis, then it ends with a right parenthesis, which matches the leftmost left parenthesis in θ.
>
> **Proof**: Here we also proceed by induction on the number of instances of (2)-(7) used to construct the formula. Clearly, the Lemma holds for atomic formulas, since they have no parentheses. Suppose, then, that the Lemma holds for formulas constructed with n or fewer instances of (2)-(7), and let θ be constructed with n+1 instances. If the last clause applied was (3)-(5), then the Lemma holds since θ itself begins with a left parenthesis and ends with the matching right parenthesis. If the last clause applied was (2), then θ is $\neg\psi$, and

the induction hypothesis applies to ψ. Similarly, if the last clause applied was (6) or (7), then θ consists of a quantifier, a variable, and a formula to which we can apply the induction hypothesis. It follows that the Lemma holds for θ.

Lemma 4. Each formula contains at least one atomic formula.

The proof proceeds by induction on the number of instances of (2)-(7) used to construct the formula, and we leave it as an exercise.

Theorem 5. Let α, β be nonempty sequences of characters on our alphabet, such that $\alpha\beta$ (i.e α followed by β) is a formula. Then α is *not* a formula.

Proof: By Theorem 1 and Lemma 3, if α contains a left parenthesis, then the right parenthesis that matches the leftmost left parenthesis in $\alpha\beta$ comes at the end of $\alpha\beta$, and so the matching right parenthesis is in β. So, α has more left parentheses than right parentheses. By Theorem 1, α is not a formula. So now suppose that α does not contain any left parentheses. By Lemma 2, $\alpha\beta$ consists of a string of zero or more unary markers followed by either an atomic formula or a formula produced using a binary connective, via one of clauses (3)-(5). If the latter formula was produced via one of clauses (3)-(5), then it begins with a left parenthesis. Since α does not contain any parentheses, it must be a string of unary markers. But then α does not contain any atomic formulas, and so by Lemma 4, α is not a formula. The only case left is where $\alpha\beta$ consists of a string of unary markers followed by an atomic formula, either in the form t_1=t_2 or $Pt_1 \ldots t_n$. Again, if α just consisted of unary markers, it would not be a formula, and so α must consist of the unary markers that start $\alpha\beta$, followed by either t_1 by itself, t_1= by itself, or the predicate letter P, and perhaps some (but not all) of the terms $t_1, \ldots, t_n$. In the first two cases, α does not contain an atomic formula, by the policy that the categories do not overlap. Since P is an n-place predicate letter, by the policy that the predicate letters are distinct, P is not an m-place predicate letter for any $m \neq n$. So the part of α that consists of P followed by the terms is not an atomic formula. In all of these cases, then, α does not contain an atomic formula. By Lemma 4, α is not a formula.

We are finally in position to show that there is no amphiboly in our language.

Theorem 6. Let θ be any formula of $\mathcal{L}1K$=. If θ is not atomic, then there is one and only one among (2)-(7) that was the last clause applied to construct θ. That is, θ could not be produced by two different clauses. Moreover, no formula produced by clauses (3)-(7) is atomic.

Proof: By Clause (8), either is θ atomic or it was produced by one of clauses (2)-(7). Thus, the first symbol in θ must be either a predicate letter, a term, a unary marker, or a left

parenthesis. If the first symbol in θ is a predicate letter or term, then θ is atomic. In this case, θ was not produced by any of (2)-(7), since all such formulas begin with something other than a predicate letter or term. If the first symbol in θ is a negation sign "¬", then was θ produced by clause (2), and not by any other clause (since the other clauses produce formulas that begin with either a quantifier or a left parenthesis). Similarly, if θ begins with a universal quantifier, then it was produced by clause (6), and not by any other clause, and if θ begins with an existential quantifier, then it was produced by clause (7), and not by any other clause. The only case left is where θ begins with a left parenthesis. In this case, it must have been produced by one of (3)-(5), and not by any other clause. We only need to rule out the possibility that θ was produced by more than one of (3)-(5). To take an example, suppose that θ was produced by (3) and (4). Then θ is $(\psi_1 \,\&\, \psi_2)$ and θ is also $(\psi_3 \vee \psi_4)$, where ψ_1, ψ_2, ψ_3, and ψ_4 are themselves formulas. That is, $(\psi_1 \,\&\, \psi_2)$ is the very same formula as $(\psi_3 \vee \psi_4)$. By Theorem 5, ψ_1 cannot be a proper part of ψ_3, nor can ψ_3 be a proper part of ψ_1. So ψ_1 must be the same formula as ψ_3. But then "&" must be the same symbol as "$\vee$", and this contradicts the policy that all of the symbols are different. So θ was not produced by both Clause (3) and Clause (4). Similar reasoning takes care of the other combinations.

This result is sometimes called "unique readability". It shows that each formula is produced from the atomic formulas via the various clauses in exactly one way. If θ was produced by clause (2), then its *main connective* is the initial "¬". If θ was produced by clauses (3), (4), or (5), then its *main connective* is the introduced "&", "$\vee$", or "$\rightarrow$", respectively. If θ was produced by clauses (6) or (7), then its *main connective* is the initial quantifier. I apologize for the tedious details. I included them to indicate the level of precision and rigor for the syntax.

3. Deduction

We now introduce a *deductive system*, *D*, for our languages. As above, we define an *argument* to be a non-empty collection of formulas in the formal language, one of which is designated to be the *conclusion*. If there are any other formulas in the argument, they are its *premises*. By convention, we use "Γ", "Γ'", "Γ_1", etc, to range over sets of formulas, and we use the letters "φ", "ψ", "θ", uppercase or lowercase, with or without subscripts, to range over single formulas. We write "Γ, Γ'" for the union of Γ and Γ', and "Γ, φ" for the union of Γ with $\{\varphi\}$.

We write an argument in the form $<\Gamma, \varphi>$, where Γ is the set of premises and φ is the conclusion. Remember that Γ may be empty. We write $\Gamma \vdash \varphi$ to indicate that φ is deducible from Γ, or, in other words, that the argument $<\Gamma, \varphi>$ is deducible in *D*. We may write $\Gamma \vdash_D \varphi$ to emphasize the deductive system *D*. We write $\vdash \varphi$ or $\vdash_D \varphi$ to indicate that φ can be deduced (in *D*) from the empty set of premises.

The rules in *D* are chosen to match logical relations concerning the English analogues of the logical terminology in the language. Again, we define the deducibility relation by recursion. We start with a rule of assumptions:

> **(As)** If φ is a member of Γ, then $\Gamma \vdash \varphi$.

We thus have that $\{\varphi\} \vdash \varphi$; each premise follows from itself. We next present two clauses for each connective and quantifier. The clauses indicate how to "introduce" and "eliminate" formulas in which each symbol is the main connective.

First, recall that "&" is an analogue of the English connective "and". Intuitively, one can deduce a formula in the form (θ & ψ) if one has deduced θ and one has deduced ψ. Conversely, one can deduce θ from (θ & ψ) and one can deduce ψ from (θ & ψ):

> **(&I)** If $\Gamma_1 \vdash \theta$ and $\Gamma_2 \vdash \psi$, then $\Gamma_1, \Gamma_2 \vdash$ (θ & ψ).

> **(&E)** If $\Gamma \vdash$ (θ & ψ) then $\Gamma \vdash \theta$; and if $\Gamma \vdash$ (θ & ψ) then $\Gamma \vdash \psi$.

The name "&I" stands for "&-introduction"; "&E" stands for "&-elimination".

Since, the symbol "$\vee$" corresponds to the English "or", $(\theta \vee \psi)$ should be deducible from θ, and $(\theta \vee \psi)$ should also be deducible from ψ:

> ($\vee$**I**) If $\Gamma \vdash \theta$ then $\Gamma \vdash (\varphi \vee \psi)$; if $\Gamma \vdash \psi$ then $\Gamma \vdash (\theta \vee \psi)$.

The elimination rule is a bit more complicated. Suppose that "θ or ψ" is true. Suppose also that φ follows from θ and that φ follows from ψ. One can reason that if θ is true, then φ is true. If instead ψ is true, we still have that φ is true. So either way, φ must be true.

> ($\vee$**E**) If $\Gamma_1 \vdash (\theta \vee \psi)$, $\Gamma_2, \theta \vdash \varphi$ and $\Gamma_3, \psi \vdash \varphi$, then $\Gamma_1, \Gamma_2, \Gamma_3 \vdash \varphi$.

For the next clauses, recall that the symbol "$\rightarrow$" is an analogue of the English "if . . . then . . . " construction. If one knows, or assumes $(\theta \rightarrow \psi)$ and also knows, or assumes θ, then one can conclude ψ. Conversely, if one deduces ψ from an assumption θ, then one can conclude that $(\theta \rightarrow \psi)$.

> ($\rightarrow$**I**) If $\Gamma, \theta \vdash \psi$, then $\Gamma \vdash (\theta \rightarrow \psi)$.

> ($\rightarrow$**E**) If $\Gamma_1 \vdash (\theta \rightarrow \psi)$ and $\Gamma_2 \vdash \theta$, then $\Gamma_1, \Gamma_2 \vdash \psi$.

Our next clauses are for the negation sign, "¬". The underlying idea is that a formula ψ is inconsistent with its negation $\neg\psi$. They cannot both be true. We call a pair of formulas ψ, $\neg\psi$ *contradictory opposites*. If one can deduce such a pair from an assumption θ, then one can conclude that θ is false, or, in other words, one can conclude $\neg\theta$.

> **(¬I)** If $\Gamma_1, \theta \vdash \psi$ and $\Gamma_2, \theta \vdash \neg\psi$, then $\Gamma_1, \Gamma_2 \vdash \neg\theta$.

There is some controversy over the other rule for the negation sign.

By (As), we have that $\{A,\neg A\} \vdash A$ and $\{A,\neg A\} \vdash \neg A$. So by ¬I we have that $\{A\} \vdash \neg\neg A$. However, we do not have the converse yet. Intuitively, $\neg\neg\theta$ corresponds to "it is not the case that it is not the case that" . One might think that this last is equivalent to θ, and we have a rule to that effect:

> **(DNE)** If $\Gamma \vdash \neg\neg\theta$, then $\Gamma \vdash \theta$.

The name DNE stands for "double-negation elimination". This inference is rejected by philosophers and mathematicians who do not hold that each meaningful sentence is either true or not true. *Intuitionistic logic* does not sanction the inference in question (see, for example Dummett [1977]), but, again, classical logic does.

To illustrate the parts of the deductive system *D* presented thus far, I show that $\vdash(A \vee \neg A)$:

> (i) $\{\neg(A \vee \neg A), A\} \vdash \neg(A \vee \neg A)$, by (As)
>
> (ii) $\{\neg(A \vee \neg A), A\} \vdash A$, by clause (As).
>
> (iii) $\{\neg(A \vee \neg A), A\} \vdash (A \vee \neg A)$, by (∨I), from (ii).
>
> (iv) $\{\neg(A \vee \neg A)\} \vdash \neg A$, by (¬I), from (i) and (iii).
>
> (v) $\{\neg(A \vee \neg A), \neg A\} \vdash \neg(A \vee \neg A)$, by (As)
>
> (vi) $\{\neg(A \vee \neg A), \neg A\} \vdash \neg A$, by (As)
>
> (vii) $\{\neg(A \vee \neg A), \neg A\} \vdash (A \vee \neg A)$, by (∨I), from (vi).
>
> (viii) $\{\neg(A \vee \neg A)\} \vdash \neg\neg A$, by (¬I), from (v) and (vii).
>
> (ix) $\vdash \neg\neg(A \vee \neg A)$, by (¬I), from (iv) and (viii).

(x) $\vdash (A \vee \neg A)$, by (DNE), from (ix).

The principle $(\theta \vee \neg\theta)$ is sometimes called the *law of excluded middle*. It is not valid in intuitionistic logic.

Let θ, $\neg\theta$ be a pair of contradictory opposites, and let ψ be any formula at all. By (As) we have $\{\theta, \neg\theta, \neg\psi\} \vdash \theta$ and $\{\theta, \neg\theta, \neg\psi\} \vdash \neg\theta$. So by (¬I), $\{\theta, \neg\theta\} \vdash \neg\neg\psi$. So, by (DNE) we have $\{\theta, \neg\theta\} \vdash \psi$. That is, anything at all follows from a pair of contradictory opposites. Some logicians introduce a rule to codify a similar inference:

If $\Gamma_1 \vdash \theta$ and $\Gamma_2 \vdash \neg\theta$, then for any formula ψ, $\Gamma_1, \Gamma_2 \vdash \psi$

The inference is sometimes called *ex falso quodlibet*. Some call it "¬-elimination", but perhaps this stretches the notion of "elimination" a bit. We do not officially include *ex falso quodlibet* as a separate rule in *D*, but as will be shown below (Theorem 10), each instance of it is derivable.

Some logicians object to *ex falso quodlibet*, on the ground that the formula ψ may be *irrelevant* to any of the premises in Γ. Suppose, for example, that one starts with some premises Γ about human nature and facts about certain people, and then deduces both the sentence "Clinton had extra-marital sexual relations" and "Clinton did not have extra-marital sexual relations". One can surely conclude that there is something wrong with premises Γ. But should we be allowed to then deduce *anything at all* from Γ? Should we be allowed to deduce "The economy is sound"?

Deductive systems that demur from *ex falso quodlibet* are part of *relevance logic*. See Anderson and Belnap [1975], Anderson, Belnap, and Dunn [1992], and Tennant [1987]. Deep philosophical issues concerning the nature of logical consequence are involved. Far be it for an article in a philosophy encyclopedia to avoid philosophical issues, but space considerations preclude a fuller treatment of this issue here. Suffice it to note that the inference is sanctioned in systems of *classical logic*, the subject of this article. It is essential to establishing the balance between the deductive system and the semantics (see §5 below).

The next pieces of *D* are the clauses for the quantifiers. Let θ be a formula, *v* a variable, and *t* a term (i.e., a variable or a constant). The define $\theta(v|t)$ to be the result of substituting *t* for each *free* occurrence of *v* in θ. So, if θ is $(Qx \,\&\, \exists xPxy)$, then $\theta(x|c)$ is $(Qc \,\&\, \exists xPxy)$. The last occurrence of *x* is not free (but recall that we avoid using formulas like this).

We have one other nicety to attend to. Suppose that v_1 and v_2 are variables. It may happen that some of the substituted instances of v_2 are bound in $\theta(v_1|v_2)$. When this happens, we say that there is a *clash* of the variables. Suppose, for example, that θ is $\exists y(\neg x = y)$, and so $\theta(x|y)$ is $\exists y(\neg y = y)$. We say that a term *t* is *free for* a variable *v* in θ if either *t* is a constant or there is no clash of variables in $\theta(v|t)$. The idea is

that no substituted instance of t should become a bound variable in $\theta(v|t)$.

A formula in the form $\forall v\ \theta$ is an analogue of the English "for every v, θ holds". So one should be able to infer $\theta(v|t)$ from $\forall v\ \theta$:

> (∀**E**) If $\Gamma \vdash \forall v\ \theta$, then $\Gamma \vdash \theta(v|t)$, provided that t is free for v in θ.

The idea here is that if $\forall v\ \theta$ is true, then θ should hold of t, no matter what t is. We can illustrate the restriction on (∀E) as follows: The sentence $\forall x\ \exists\ y(\neg x{=}y)$ corresponds to an assertion that for every object x, there is an object different from x. This is a coherent, plausible assertion. It is true if and only if the universe has at least two objects. It should follow that no matter what object t may be, something is different from t. However, if we were allowed to substitute the variable y for x, we would conclude $\exists y(\neg y{=}y)$, which says that there is something which is different from itself, a blatant falsehood.

The introduction clause for the universal quantifier is a bit more complicated. Suppose that a formula θ has a variable v free, and that θ has been deduced from a set of premises Γ. If the variable v does not occur free in any member of Γ, then θ will hold no matter which object v may denote. That is, $\forall v\ \theta$ follows.

> (∀**I**) If $\Gamma \vdash \theta$ and the variable v does not occur free in any member of Γ, then $\Gamma \vdash \forall v\theta$.

This introduction rule corresponds to a common inference in mathematics. Suppose that a mathematician says "let n be a natural number" and goes on to show that n has a certain property P, without assuming anything about n (except that it is a natural number). She then reminds the reader that n is "arbitrary", and concludes that P holds for *all* natural numbers. The condition that the variable v not occur in any premise is what guarantees that it is indeed "arbitrary". It could be any object, and so anything we conclude about it holds for all objects.

The existential quantifier is an analogue of the English expression "there exists", or perhaps just "there is". If we have established (or assumed) that a given object t has a given property, then it follows that there is something that has that property. Again, we have to be careful with the syntax, and avoid clashes of variables.

> (∃**I**) If $\Gamma \vdash \theta$, then $\Gamma \vdash \exists v\ \theta'$, where θ' is obtained from θ by substituting the variable v for zero or more occurrences of a term t, provided that (1) if t is a variable, then all of the replaced occurrences of t are free in θ, and (2) all of the substituted occurrences of v are free in θ'.

The provision (1) keeps us from replacing bound variables. The provision (2) comes up only if v is bound by another quantifier in θ. As noted above, we avoid such formulas (since they appear to bind the same occurrence twice).

The elimination rule for ∃ is not quite as simple:

> (**∃E**) If $\Gamma_1 \vdash \exists v\, \theta$ and $\Gamma_2, \theta \vdash \varphi$, then $\Gamma_1, \Gamma_2 \vdash \varphi$, provided that *v* does not occur free in φ, nor in any member of Γ_2.

This elimination rule also corresponds to a common inference. Suppose that a mathematician asserts that there is a natural number with a given property *P*. She then says "let *n* be such a natural number, so that *Pn*", and goes on to establish a sentence φ, which does not mention the number *n*. If the derivation of φ does not invoke anything about *n* (other than the assumption that it has the given property *P*), then *n* could have been any number that has the property *P*. That is, *n* is an *arbitrary* number with property *P*. It does not matter which number *n* is. Since φ does not mention *n*, it follows from the assertion that something has property *P*. The provisions added to (∃E) are to guarantee that *x* is "arbitrary".

As noted in the previous section, some authors introduce different letters for bound variables and (what amounts to) free variables. This makes the syntax slightly more complex, but simplifies the provisions on some of the rules of inference. Writers of logic books often face tradeoffs like this.

The final items are the rules for the identity sign "=". The introduction rule is about a simple as can be:

> **(=I)** $\Gamma \vdash t{=}t$, where *t* is any term.

This "inference" corresponds to the truism that everything is identical to itself. The elimination rule corresponds to a principle that if *a* is identical to *b*, then anything true of *a* is also true of *b*, again paying attention to clashes of variables.

> **(=E)** If $\Gamma_1 \vdash t_1{=}t_2$ and $\Gamma_2 \vdash \theta$, then $\Gamma_1, \Gamma_2 \vdash \theta'$, where θ' is obtained from θ by replacing zero or more occurrences of t_1 with t_2, provided that no bound variables are replaced, and if t_2 is a variable, then all of its substituted occurrences are free.

The rule (=E) indicates a certain restriction in the expressive resources of our language. Suppose, for example, that Harry is identical to Donald (since his mischievous parents gave him two names). It would not follow from this and "Dick knows that Harry is wicked" that "Dick knows that Donald is wicked", for the reason that Dick might not know that Harry is identical to Donald. Contexts like this, in which identicals cannot safely be substituted for each other, are called "opaque". We assume that our language $\mathcal{L}1K{=}$ has no opaque contexts.

One final clause completes the description of the deductive system *D*:

> **(*)** That's all folks. $\Gamma \vdash \theta$ only if θ follows from members of Γ by the above rules.

Again, this clause allows proofs by induction on the rules used to establish an inference. If a property of arguments holds of all instances of (As) and (=I), and if the other rules preserve the property, then every argument that is deducible in *D* enjoys the property in question.

Before moving on to the model theory for $\mathcal{L}1K$=, we pause to note a few features of the deductive system.

Lemma 7. Suppose that $\Gamma \vdash_D \varphi$, and let v' be a variable that does not occur free in φ or in any member of Γ. Assume that v' is free for v in φ and in every member of Γ. Let Γ' be $\{\theta(v|v') \mid \theta \in \Gamma\}$. That is, Γ' is the result of replacing every free occurrence of a variable v with v' in every member of Γ. Then $\Gamma' \vdash_D \varphi(v|v')$.

Proof: The proof of this lemma is tedious, but we give its essentials. We proceed by induction on the number of rules that were used to arrive at $\Gamma \vdash \varphi$. Suppose that n>0 is a natural number, and that the lemma holds for any argument that was derived using fewer than n rules, and suppose that $\Gamma \vdash \varphi$ using exactly n rules. If n=1, then the rule applied is either (As) or (=I). In this case, $\Gamma' \vdash \varphi(v|v')$ by the same rule. If the last rule applied is (&I), then φ has the form $(\theta \,\&\, \psi)$, and we have $\Gamma_1 \vdash \theta$ and $\Gamma_2 \vdash \psi$, with $\Gamma = \Gamma_1, \Gamma_2$. We apply the induction hypothesis to the deductions of θ and ψ, and then apply (&I) to the result. If the last rule applied was (&E), we have two sub-cases, but they are symmetric. We have $\Gamma \vdash (\varphi \,\&\, \psi)$. There are two slight complications here: the new variable v' may occur free in ψ and it may not be free for v in ψ. In either case, first pick a new variable u that does not occur (free or bound) in $(\varphi \,\&\, \psi)$ or in any member of Γ. Now apply the induction hypothesis, substituting u for v' in the deduction $\Gamma \vdash (\varphi \,\&\, \psi)$. Since v' does not occur free in φ or in any member of Γ, those formulas are left unchanged. The maneuver removes any free occurrences of v' from the subformula ψ. Now apply the induction hypothesis to the result, substituting v' for v, and then apply (&E). The remaining cases are similar.

Theorem 8. The rule of Weakening. If $\Gamma_1 \vdash \varphi$ and $\Gamma_1 \subseteq \Gamma_2$, then $\Gamma_2 \vdash \varphi$.

Proof: Again, we proceed by induction on the number of rules that were used to arrive at $\Gamma_1 \vdash \varphi$. Suppose that n>0 is a natural number, and that the theorem holds for any argument that was derived using fewer than n rules. Suppose that $\Gamma_1 \vdash \varphi$ using exactly n rules. If n=1, then the rule is either (As) or (=I). In these cases, $\Gamma_2 \vdash \varphi$ by the same rule. If the last rule applied was (&I), then φ has the form $(\theta \& \psi)$, and we have $\Gamma_3 \vdash \theta$ and $\Gamma_4 \vdash \psi$, with $\Gamma_1 = \Gamma_3, \Gamma_4$. We apply the induction hypothesis to the deductions of θ and ψ, to get $\Gamma_2 \vdash \theta$ and $\Gamma_2 \vdash \psi$. and then apply (&I) to the result to get $\Gamma_2 \vdash \varphi$. Most of the other cases are

exactly like this. Slight complications arise only in the rules (∀I) and (∃E), because there we have to pay attention to the conditions for the rules. Starting with (∃E), we have $\Gamma_3 \vdash \exists v \theta$ and $\Gamma_4, \theta \vdash \varphi$, with Γ_1 being Γ_3, Γ_4, and v not free in φ, nor in any member of Γ_4. We apply the induction hypothesis to get $\Gamma_2 \vdash \exists v \theta$, and then (∃E) to end up with $\Gamma_2 \vdash \varphi$. Suppose that the last rule applied to get $\Gamma_1 \vdash \varphi$ is (∀I). So φ is a formula in the form $\forall v \theta$, and we have $\Gamma_1 \vdash \theta$ and the variable v does not occur free in any member of Γ_1. The problem is that v may occur free in a member of Γ_2, and so we cannot just invoke the induction hypothesis and apply (∀I) to the result. Let v' be a variable that does not occur (free or bound) in θ or in any member of Γ_2, and let Γ' be the result of substituting v for every free occurrence of v in Γ_2. Since v does not occur free in any member of Γ_1, we still have $\Gamma_1 \subseteq \Gamma$. The induction hypothesis gives us $\Gamma' \vdash \theta$, and now we apply (∀I) to get $\Gamma' \vdash \varphi$. We now apply Lemma 7, substituting v for the new variable v. The result is $\Gamma_2 \vdash \varphi$.

Theorem 8 allows us to add on premises at will. It follows that $\Gamma \vdash \varphi$ if and only if there is a subset $\Gamma' \subseteq \Gamma$ such that $\Gamma' \vdash \varphi$. By clause (*), all derivations are established in a finite number of steps. So we have

Theorem 9. $\Gamma \vdash \varphi$ if and only if there is a finite $\Gamma' \subseteq \Gamma$ such that $\Gamma' \vdash \varphi$.

Theorem 10. The rule of ex falso quodlibet is a "derived rule" of *D*. That is, if $\Gamma_1 \vdash \theta$ and $\Gamma_2 \vdash \neg\theta$, then $\Gamma_1, \Gamma_2 \vdash \psi$, for any formula ψ.

Proof: Suppose that $\Gamma_1 \vdash \theta$ and $\Gamma_2 \vdash \neg\theta$. Then by Theorem 8, $\Gamma_1, \neg\psi \vdash \theta$, and $\Gamma_2, \neg\psi \vdash \theta$. So by (¬I), $\Gamma_1, \Gamma_2 \vdash \neg\neg\psi$. By (DNE), $\Gamma_1, \Gamma_2 \vdash \psi$.

Theorem 11. The rule of Cut. If $\Gamma_1 \vdash \psi$ and $\Gamma_2, \psi \vdash \theta$, then $\Gamma_1, \Gamma_2 \vdash \theta$.

Proof: Suppose $\Gamma_1 \vdash \psi$ and $\Gamma_2, \psi \vdash \theta$. We proceed by induction on the number of rules used to establish $\Gamma_2, \psi \vdash \theta$. Suppose that *n* is a natural number, and that the theorem holds for any argument that was derived using fewer than *n* rules. Suppose that $\Gamma_2, \psi \vdash \theta$ was derived using exactly *n* rules. If the last rule used was (=I), then $\Gamma_1, \Gamma_2 \vdash \theta$ is also an instance of (=I). If $\Gamma_2, \psi \vdash \theta$ is an instance of (As), then either θ is ψ, or θ is a member of Γ_2. In the former case, we have $\Gamma_1 \vdash \theta$ by supposition, and get $\Gamma_1, \Gamma_2 \vdash \theta$ by Weakening (Theorem 8). In the latter case, $\Gamma_1, \Gamma_2 \vdash \theta$ is itself an instance of (As). Suppose that $\Gamma_2, \psi \vdash \theta$ was obtained using (&E). Then we have $\Gamma_2, \psi \vdash (\theta \& \varphi)$. The induction hypothesis gives us $\Gamma_1, \Gamma_2 \vdash (\theta \& \varphi)$, and (&E) produces $\Gamma_1, \Gamma_2 \vdash \theta$. The remaining cases

are similar.

Theorem 11 allows us to chain together inferences. This fits the practice of establishing theorems and lemmas and then using those theorems and lemmas later, at will. The cut principle is, I think, essential to reasoning. In some logical systems, the cut principle is a deep theorem. The system here was designed to make the proof of Theorem 11 straightforward.

If $\Gamma \vdash_D \theta$, then we say that the formula θ is a *deductive consequence* of the set of formulas Γ, and that the argument $<\Gamma,\theta>$ is *deductively valid*. A formula θ is a *logical theorem*, or a *deductive logical truth*, if $\vdash_D \theta$. That is, θ is a logical theorem if it is a deductive consequence of the empty set. A set Γ of formulas is *consistent* if there is no formula θ such that $\Gamma \vdash_D \theta$ and $\Gamma \vdash_D \neg\theta$. That is, a set is consistent if it does not entail a pair of contradictory opposite formulas.

Theorem 12. A set Γ is consistent if and only if there is a formula θ such that it is not the case that $\Gamma \vdash \theta$.

Proof: Suppose that Γ is consistent and let θ be any formula. Then either it is not the case that $\Gamma \vdash \theta$ or it is not the case that $\Gamma \vdash \neg\theta$. For the converse, suppose that Γ is inconsistent and let ψ be any formula. We have that there is a formula such that both $\Gamma \vdash \theta$ and $\Gamma \vdash \neg \theta$. By ex falso quodlibet (Theorem 10), $\Gamma \vdash \psi$.

Define a set Γ of formulas of the language $\mathcal{L}1K$= to be *maximally consistent* if Γ is consistent and for every formula θ of $\mathcal{L}1K$=, if θ is not in Γ, then Γ, θ is inconsistent. In other words, Γ is maximally consistent if Γ is consistent, and adding any formula in the language not already in Γ renders it inconsistent. Notice that if Γ is maximally consistent then $\Gamma \vdash \theta$ if and only if θ is in Γ.

Theorem 13. The Lindenbaum Lemma. Let Γ be any consistent set of formulas of $\mathcal{L}1K$=. Then there is a set Γ' of formulas of $\mathcal{L}1K$= such that $\Gamma \subseteq \Gamma'$ and Γ' is maximally consistent.

Proof: Although this theorem holds in general, we assume here that the set *K* of non-logical terminology is either finite or denumerably infinite (i.e., the size of the natural numbers, usually called $\aleph_0$). It follows that there is an enumeration $\theta_0, \theta_1, \ldots$ of the formulas of $\mathcal{L}1K$=, such that every formula of $\mathcal{L}1K$= eventually occurs in the list. Define a sequence of sets of formulas, by recursion, as follows: Γ_0 is Γ; for each natural number *n*, if Γ_n, θ_n is consistent, then let $\Gamma_{n+1} = \Gamma_n, \theta_n$. Otherwise, let $\Gamma_{n+1} = \Gamma_n$. Let Γ' be the union of all of the sets Γ_n. Intuitively, the idea is to go through the formulas of $\mathcal{L}1K$=, throwing each one into Γ' if doing so produces a consistent set. Notice that each Γ_n is consistent. Suppose that Γ' is inconsistent. Then there is a formula θ such that $\Gamma' \vdash \theta$ and

$\Gamma' \vdash \neg\theta$. By Theorem 9 and Weakening (Theorem 8), there is finite subset Γ'' of Γ' such that $\Gamma'' \vdash \theta$ and $\Gamma'' \vdash \neg\theta$. Because Γ'' is finite, there is a natural number *n* such that every member of Γ'' is in Γ_n. So, by Weakening again, $\Gamma_n \vdash \theta$ and $\Gamma_n \vdash \neg\theta$. So Γ_n is inconsistent, which contradicts the construction. So Γ' is consistent. Now suppose that a formula θ is not in Γ'. We have to show that Γ', θ is inconsistent. The formula θ must occur in the aforementioned list of formulas; say that θ is θ_m. Since θ_m is not in Γ', then it is not in Γ_{m+1}. This happens only if Γ_m, θ_m is inconsistent. So a pair of contradictory opposites can be deduced from Γ_m, θ_m. By Weakening, a pair of contradictory opposites can be deduced from Γ', θ_m. So Γ', θ_m is inconsistent. Thus, Γ' is maximally consistent.

Notice that this proof uses a principle corresponding to the law of excluded middle. In the construction of Γ', we assumed that, at each stage, either Γ_n is consistent or it is not. Intuitionists, who demur from excluded middle, do not accept the Lindenbaum lemma (see Shapiro [1988]).

4. Semantics

Let *K* be a set of non-logical terminology. An *interpretation* for the language $\mathcal{L}1K$= is a structure *M* = <*d*,*I*>, where *d* is a non-empty set, called the *domain-of-discourse*, or simply the *domain*, of the interpretation, and *I* is an *interpretation function*. Informally, the domain is what we interpret the language $\mathcal{L}1K$= to be about. It is what the variables range over. The interpretation function assigns appropriate extensions to the non-logical terms. In particular,

> If *c* is a constant in *K*, then *I*(*c*) is a member of the domain *d*.

> If P^0 is a zero-place predicate letter in *K*, then $I(P^0)$ is a truth value, either truth or falsehood.

> If Q^1 is a one-place predicate letter in *K*, then *I*(*Q*) is a subset of *d*. Intuitively, *I*(*Q*) is the set of members of the domain that the predicate *Q* holds of. If *Q* represents "red", then *I*(*Q*) might be the red members of the domain.

> If R^2 is a two-place predicate letter in *K*, then *I*(*R*) is a set of ordered pairs of members of *d*. Intuitively, *I*(*R*) is the set of pairs of members of the domain that the relation *R* holds between. If *R* represents "love", then *I*(*R*) might consist of the pairs <*a*,*b*>, such that *a* loves *b*.

> In general, if S^n is an *n*-place predicate letter in *K*, then *I*(*S*) is a set of ordered *n*-tuples of members of *d*.

Define *s* to be a *variable-assignment*, or simply an *assignment*, on an interpretation *M*, if *s* is a function

from the variables to the domain *d* of *M*. The role of variable-assignments is to assign denotations to the *free* variables of open formulas. (In a sense, the quantifiers determine the "meaning" of the bound variables.) Logical systems that dispense with free variables do not need variable-assignments, but some other device is employed.

We now define a relation of *satisfaction* between interpretations, variable-assignments, and formulas of $\mathcal{L}1K$=. If φ is a formula of $\mathcal{L}1K$=, *M* is an interpretation for $\mathcal{L}1K$=, and *s* is a variable-assignment on *M*, then we write $M,s \vDash \varphi$ for *M satisfies* φ *under the assignment s*. The idea is that $M,s \vDash \varphi$ is an analogue of "φ comes out true when interpreted as in *M* via *s*".

Let *t* be a term of $\mathcal{L}1K$=. We define the *denotation* of *t* in *M* under *s*, in terms of the interpretation function and variable-assignment:

> If *c* is a constant, then $D_{M,s}(c)$ is $I(c)$, and if *v* is a variable, then $D_{M,s}(v)$ is $s(v)$.

That is, the interpretation *M* assigns denotations to the constants, while the variable-assignment assigns denotations to the (free) variables. If the language contained function symbols, the denotation function would be defined by recursion.

We now proceed by recursion on the complexity of the formulas of $\mathcal{L}1K$=.

> If t_1 and t_2 are terms, then $M,s \vDash t_1=t_2$ if and only if $D_{M,s}(t_1)$ is the same as $D_{M,s}(t_2)$.

This is about as straightforward as it gets. An identity $t_1=t_2$ comes out true if and only if the terms t_1 and t_2 denote the same thing.

> If P^0 is a zero-place predicate letter in *K*, then $M,s \vDash P$ if and only if $I(P)$ is truth.

> If S^n is an *n*-place predicate letter in *K* and $t_1, \ldots, t_n$ are terms, then $M,s \vDash St_1 \ldots t_n$ if and only if the *n*-tuple $\langle D_{M,s}(t_1), \ldots, D_{M,s}(t_n)\rangle$ is in $I(S)$.

This takes care of the atomic formulas. We now proceed to the compound formulas of the language, following the meanings of the English counterparts of the logical terminology.

> $M,s \vDash \neg\theta$ if and only if it is not the case that $M,s \vDash \theta$.

> $M,s \vDash (\theta \& \psi)$ if and only if both $M,s \vDash \theta$ and $M,s \vDash \psi$.

> $M,s \vDash (\theta \vee \psi)$ if and only if either $M,s \vDash \theta$ or $M,s \vDash \psi$.

$M,s \vDash (\theta \rightarrow \psi)$ if and only if either it is not the case that $M,s \vDash \theta$, or $M,s \vDash \psi$.

$M,s \vDash \forall v\theta$ if and only if $M,s' \vDash \theta$, for every assignment s' that agrees with s except possibly at the variable v.

The idea here is that $\forall v\theta$ comes out true if and only if θ comes out true no matter what is assigned to the variable v. The final clause is similar.

$M,s \vDash \exists v\theta$ if and only if $M,s' \vDash \theta$, for some assignment s' that agrees with s except possibly at the variable v.

So $\exists v\theta$ comes out true if there is an assignment to v that makes θ true.

Theorem 6, unique readability, assures us that this definition is coherent. At each stage in breaking down a formula, there is exactly one clause to be applied, and so we never get contradictory verdicts concerning satisfaction.

As indicated, the role of variable-assignments is to give denotations to the free variables. We now show that variable-assignments play no other role.

Theorem 14. For any formula θ, if s_1 and s_2 agree on the free variables in θ, then $M,s_1 \vDash \theta$ if and only if $M,s_2 \vDash \theta$.

Proof: We proceed by induction on the complexity of the formula θ. The theorem clearly holds if θ is atomic, since in those cases only the values of the variable-assignments at the variables in θ figure in the definition. Assume, then, that the theorem holds for all formulas less complex than θ. And suppose that s_1 and s_2 agree on the free variables of θ. Assume, first, that θ is a negation, $\neg\psi$. Then, by the induction hypothesis, $M,s_1 \vDash \psi$ if and only if $M,s_2 \vDash \psi$. So, by the clause for negation, $M,s_1 \vDash \neg\psi$ if and only if $M,s_2 \vDash \neg\psi$. The cases where the main connective in θ is a binary connectives are also straightforward. Suppose that θ is $\exists v\psi$, and that $M,s_1 \vDash \exists v\psi$. Then there is an assignment $s_1{}'$ that agrees with s_1 except possibly at v such that $M,s_1{}' \vDash \psi$. Let $s_2{}'$ be the assignment that agrees with s_2 on the free variables not in and agrees with $s_1{}'$ on the others. Then, by the induction hypothesis, $M,s_2{}' \vDash \psi$. Notice that $s_2{}'$ agrees with s_2 on every variable except possibly v. So $M,s_2 \vDash \exists v\psi$. The converse is the same, and the case where θ begins with a universal quantifier is similar.

Recall that a sentence is a formula with no free variables. So by Theorem 14, if θ is a sentence, and s_1, s_2, are any two variable-assignments, then $M,s_1 \vDash \theta$ if and only if $M,s_2 \vDash \theta$. So we can just write $M \vDash \theta$ if

$M,s \vDash \theta$ for some, or all, variable-assignments s.

Suppose that $K' \subseteq K$ are two sets of non-logical terms. If $M = \langle d,I \rangle$ is an interpretation of $\mathcal{L}1K$=, then we define the *restriction* of M to $\mathcal{L}1K'$ be the interpretation $M'=\langle d,I' \rangle$ such that I' is the restriction of I to K'. That is, M and M' have the same domain and agree on the non-logical terminology in K'. A straightforward induction establishes the following:

> **Theorem 15**. If M' is the restriction of M to $\mathcal{L}1K'$, then for every formula θ of $\mathcal{L}1K'$, if s is any variable-assignment, $M,s \vDash \theta$ if and only if $M',s \vDash \theta$.

> **Theorem 16.** If two interpretations M_1, M_2 have the same domain and agree on the non-logical terminology of a formula θ, then if s is any variable-assignment, $M_1,s \vDash \theta$ if and only if $M_2,s \vDash \theta$.

In short, the satisfaction of a formula θ only depends on the domain of discourse, the interpretation of the non-logical terminology in θ, and the assignments to the free variables in θ.

We say that an argument $\langle \Gamma,\theta \rangle$ is *semantically valid*, or just *valid*, written $\Gamma \vDash \theta$, if for every interpretation M of the language and any variable-assignment s on M, if $M,s \vDash \psi$, for every member ψ of Γ, then $M,s \vDash \theta$. If $\Gamma \vDash \theta$, we also say that θ is a *logical consequence*, or *semantic consequence*, or *model-theoretic consequence* of Γ. The definition corresponds to the informal idea that an argument is valid if it is not possible for its premises to all be true and its conclusion false. Our definition of logical consequence also sanctions the common thesis that a valid argument is truth-preserving--to the extent that satisfaction represents truth. Officially, an argument in $\mathcal{L}1K$= is valid if its conclusion comes out true under every interpretation of the language in which the premises are true. Validity is the model-theoretic counterpart to deducibility.

A formula θ is *logically true*, or *valid*, if $M,s \vDash \theta$, for every interpretation M and assignment s. A formula is logically true if and only if it is a consequence of the empty set. If θ is logically true, then for any set Γ of formulas, $\Gamma \vDash \theta$. Logical truth is the model-theoretic counterpart of theoremhood.

A formula θ is *satisfiable* if there is an interpretation M and a variable-assignment s on M such that $M,s \vDash \theta$. That is, θ is satisfiable if there is an interpretation and assignment that satisfies it. A set Γ of formulas is satisfiable if there is an interpretation M and a variable-assignment s on M such that $M,s \vDash \theta$, for every formula θ in Γ. If Γ is a set of sentences and if $M \vDash \theta$ for each sentence θ in Γ, then we say that M is a *model of* Γ. So a set of sentences is satisfiable if it has a model. Satisfiability is the model-theoretic counterpart to consistency.

Notice that $\Gamma \vDash \theta$ if and only if the set $\Gamma,\neg\theta$ is not satisfiable. It follows that if a set Γ is not satisfiable, then if θ is any formula, $\Gamma \vDash \theta$. This is a model-theoretic counterpart to ex falso quodlibet (see Theorem 10). We have the following, as an analogue to Theorem 12:

Theorem 17. Let Γ be a set of formulas. The following are equivalent: (a) Γ is satisfiable; (b) there is no formula θ such that both $\Gamma \vDash \theta$ and $\Gamma \vDash \neg\theta$; (c) there is some formula ψ such that it is not the case that $\Gamma \vDash \psi$.

Proof: (a) $\Rightarrow$ (b): Suppose that Γ is satisfiable and let θ be any formula. There is an interpretation *M* and assignment *s* such that *M*,*s* $\vDash \psi$ for every member ψ of Γ. By the clause for negations, we cannot have both *M*,*s* $\vDash \theta$ and *M*,*s* $\vDash \neg\theta$. So either $\langle\Gamma,\theta\rangle$ is not valid or else $\langle\Gamma,\neg\theta\rangle$ is not valid. (b) $\Rightarrow$ (c): This is immediate. (c) $\Rightarrow$ (a): Suppose that it is not the case that $\Gamma \vDash \psi$. Then there is an interpretation *M* and an assignment *s* such that *M*,*s* $\vDash \theta$, for every formula θ in Γ and it is not the case that *M*,*s* $\vDash \psi$. A fortiori, *M*,*s* satisfies every member of Γ, and so Γ is satisfiable.

5. Meta-theory

We now present some results that relate the deductive notions to their model-theoretic counterparts. The first one is probably the most straightforward. We motivated both the various rules of the deductive system *D* and the various clauses in the definition of satisfaction in terms of the meaning of the English counterparts to the logical terminology. So one would expect that an argument is deducible, or deductively valid, only if it is semantically valid.

Theorem 18. Soundness. For any formula θ and set Γ of formulas, if $\Gamma \vdash_D \theta$, then $\Gamma \vDash \theta$.

Proof: We proceed by induction on the number of clauses used to establish $\Gamma \vdash \theta$. So let *n* be a natural number, and assume that the theorem holds for any argument established as deductively valid with fewer than *n* steps. And suppose that $\Gamma \vdash \theta$ was established using exactly *n* steps. If the last rule applied was (=I) then θ is a formula in the form *t*=*t*, and so θ is logically true. A fortiori, $\Gamma \vDash \theta$. If the last rule applied was (As), then θ is a member of Γ, and so of course any interpretation and assignment that satisfies every member of Γ also satisfies θ. Suppose the last rule applied is (&I). So θ has the form $(\varphi \& \psi)$, and we have $\Gamma_1 \vdash \varphi$ and $\Gamma_2 \vdash \psi$, with $\Gamma = \Gamma_1, \Gamma_2$. The induction hypothesis gives us $\Gamma_1 \vDash \varphi$ and $\Gamma_2 \vDash \psi$. Suppose that *M*,*s* satisfies every member of Γ. Then *M*,*s* satisfies every member of Γ_1, and so *M*,*s* satisfies φ. Similarly, *M*,*s* satisfies every member of Γ_2, and so *M*,*s* satisfies ψ. Thus, by the clause for "&" in the definition of satisfaction, *M*,*s* satisfies θ. So $\Gamma \vDash \theta$. Suppose the last clause applied was ($\exists$E). So we have $\Gamma_1 \vDash \exists v\psi$ and $\Gamma_2, \psi \vDash \theta$, where $\Gamma = \Gamma_1, \Gamma_2$, and *v* does not occur free in ψ, nor in any member of Γ_2. By the induction hypothesis, we have $\Gamma_1 \vdash \exists v\psi$ and $\Gamma_2, \psi \vDash \theta$. Let *M* be an interpretation and *s* an assignment such that *M*,*s* satisfies every member of Γ. Then *M*,*s* satisfies every member of

Γ_1, and so $M,s \vDash \exists v\psi$. So there is an assignment s' that agrees with s on every variable except possibly v such that $M,s' \vDash \psi$. We have that M,s satisfies every member of Γ_2. Since v does not occur free in any member of Γ_2, and s agrees with s' on everything else, we have that M,s' satisfies every member of Γ_2, by Theorem 14. So $M,s' \vDash \theta$. Since v does not occur free in θ, and s agrees with s on everything else, we have that $M,s \vDash \theta$, also by Theorem 14. So, in this case, $\Gamma \vDash \theta$. Notice the role of the restrictions on (∃E) here. The other cases are about as straightforward.

Corollary 19. Let Γ be a set of formulas. If Γ is satisfiable, then Γ is consistent.

Proof: Suppose that Γ is satisfiable. So let *M* be an interpretation and *s* an assignment such that *M*,*s* satisfies every member of Γ. Assume that Γ is inconsistent. Then there is a formula θ such that $\Gamma \vdash \theta$ and $\Gamma \vdash \neg\theta$. By soundness (Theorem 18), $\Gamma \vDash \theta$ and $\Gamma \vDash \neg\theta$. So we have that $M,s \vDash \theta$ and $M,s \vDash \neg\theta$. But this is impossible, given the clause for negation in the definition of satisfaction.

Even though the deductive system *D* and the model-theoretic semantics were developed with the meanings of the logical terminology in mind, one should not automatically expect the converse to soundness (or Corollary 19) to hold. For all we know so far, we may not have included enough rules of inference to deduce every valid argument. The converses to soundness and Corollary 19 are among the most interesting results in contemporary mathematical logic. We begin with the latter.

Theorem 20. Completeness. Gödel [1930]. Let Γ be a set of formulas. If Γ is consistent, then Γ is satisfiable.

Proof: The proof of completeness is rather complex. We only sketch it here. Let Γ be a consistent set of formulas of $\mathcal{L}1K$=. Again, we assume for simplicity that the set *K* of non-logical terminology is either finite or countably infinite (although the theorem holds even if *K* is uncountable). The task at hand is to find an interpretation *M* and a variable-assignment *s* on *M*, such that *M*,*s* satisfies every member of Γ. Consider the language obtained from $\mathcal{L}1K$= by adding a denumerably infinite stock of new individual constants c_0, c_1, . . . We stipulate that the constants, c_0, c_1, . . . , are all different from each other and none of them occur in *K*. We build an interpretation of the language from the language itself, using some of the constants as members of the domain of discourse. Let θ_0, θ_1, . . . be an enumeration of the formulas of the expanded language, so that each formula occurs in the list eventually. Let *x* be any variable, and define a sequence Γ_0, Γ_1, . . . of sets of formulas (of the expanded language) by recursion as follows: $\Gamma_0 = \Gamma$; and $\Gamma_{n+1} = \Gamma_n,(\exists x\theta_n \rightarrow \theta_n(x|c_i))$, where c_i is the first constant in the above list that does not occur in θ_n or in any member of Γ_n. The underlying idea here is that if $\exists x\theta_n$is true, then c_i is to be one such *x*. Let Γ be the union of the sets Γ_n.

I sketch a proof that Γ' is consistent. Suppose that Γ' is inconsistent. By Theorem 9, there is a finite subset of Γ that is inconsistent, and so one of the sets Γ_m is inconsistent. By hypothesis, $\Gamma_0 = \Gamma$ is consistent. Let *n* be the smallest number such that Γ_n is consistent, but $\Gamma_{n+1} = \Gamma_n, (\exists x\theta_n \rightarrow \theta_n(x|c_i))$ is inconsistent. By (¬I), we have that

(1) $\Gamma_n \vdash \neg(\exists x\theta_n \rightarrow \theta_n(x|c_i))$.

By *ex falso quodlibet* (Theorem 10), $\Gamma_n, \neg\exists x\theta_n, \exists x\theta_n \vdash \theta_n(x|c_i)$. So by (→I), $\Gamma_n, \neg\exists x\theta_n \vdash (\exists x\theta_n \rightarrow \theta_n(x|c_i))$. From this and (1), we have $\Gamma_n \vdash \neg\neg\exists x\theta_n$, by (¬I), and by (DNE) we have

(2) $\Gamma_n \vdash \exists x\theta_{\mathrm{n}}$.

By (As), $\Gamma_n, \theta_n(x|c_i), \exists x\theta_n \vdash \theta_n(x|c_i)$. So by (→I), $\Gamma_n, \theta_n(x|c_i) \vdash (\exists x\theta_n \rightarrow \theta_n(x|c_i))$. From this and (1), we have $\Gamma_n \vdash \neg\theta_n(x|c_i)$, by (¬I). Let *v* be a variable that does not occur (free or bound) in θ_n or in any member of Γ_n. By uniform substitution of *v* for c_i, we can turn the derivation of $\Gamma_n \vdash \neg\theta_n(x|c_i)$ into $\Gamma_n \vdash \neg\theta_n(x|v)$. By (∀I), we have

(3) $\Gamma_n \vdash \forall v\neg\theta_n(x|v)$.

By (As) we have $\{\forall v\neg\theta_n(x|v), \theta_n\} \vdash \theta_n$ and by (∀E) we have $\{\forall v\neg\theta_n(x|v), \theta_n\} \vdash \neg\theta_n$. So $\{\forall v\neg\theta_n(x|v), \theta_n\}$ is inconsistent. Let φ be any sentence of the language (so that φ has no free variables). By ex falso quodlibet (Theorem 10), we have that $\{\forall v\neg\theta_n(x|v), \theta_n\} \vdash \varphi$ and $\{\forall v\neg\theta_n(x|v), \theta_n\} \vdash \neg\varphi$. So with (2), we have that $\Gamma_n, \forall v\neg\theta_n(x|v) \vdash \varphi$ and $\Gamma_n, \forall v\neg\theta_n(x|v) \vdash \neg\varphi$, by (∃E). By Cut (Theorem 11), $\Gamma_n \vdash \varphi$ and $\Gamma_n \vdash \neg\varphi$. So Γ_n is inconsistent, contradicting the assumption. So Γ' is consistent.

Applying the Lindenbaum Lemma (Theorem 13), let Γ'' be a maximally consistent set of sentences (of the expanded language) that contains Γ'. So, of course, Γ'' contains Γ. We define an interpretation *M*, and a variable-assignment *s* on *M*, such that *M,s* satisfies every member of Γ''.

If we did not have a sign for identity in the language, we would let the domain of *M* be the collection of new constants $\{c_0, c_1, \ldots\}$. But as it is, there may be a sentence in the form $c_i{=}c_j$, with $i \neq j$, in Γ''. If so, we cannot have both c_i and c_j in the domain of the interpretation. So we define the domain *d* of *M* to be the set $\{c_i \mid$ there is no $j<i$ such that

$c_i=c_j$ is in Γ″}. In other words, a constant c_i is in the domain of *M* if Γ″ does not declare it to be identical to an earlier constant in the list. Notice that for each new constant c_i, there is exactly one $j \leq i$ such that c_j is in *d* and the sentence $c_i=c_j$ is in Γ″.

We now define the interpretation function *I*. Let *a* be any constant in the expanded language. By (=I) and (∃I), Γ″ ⊢ ∃*x x*=*a*, and so ∃*x x*=*a* ∈ Γ″. By the construction of Γ′, there is a sentence in the form (∃*x x*=*a* → c_i=*a*) in Γ″. We have that c_i=*a* is in Γ″. As above, there is exactly one c_j in *d* such that $c_i=c_j$ is in Γ″. Let $I(a)=c_j$. Notice that if c_i is a constant in the domain *d*, then $I(c_i)=c_i$. That is each c_i in *d* denotes itself.

Let *P* be a one-place predicate letter in *K*. Let *I*(*P*) be the set of constants {c_i | c_i is in *d* and the formula *Pc* is in Γ″}. Let *R* be a binary predicate letter in *K*. Let *I*(*R*) be the set of pairs of constants {<c_i,c_j> | c_i is in *d*, c_j is in *d*, and the formula Rc_ic_j is in Γ″}. Three-place predicates, etc. are interpreted similarly. In effect, *I* interprets the non-logical terminology as they are in Γ″.

The variable-assignment is similar. If *v* is a variable, then $s(v)=c_i$, where c_i is the first constant in *d* such that $c_i=v$ is in Γ″.

The final item in this proof is a tedious lemma that for every formula θ in the expanded language, *M*,*s*⊨θ if and only if θ is in Γ″. This proceeds by induction on the complexity of θ. The case where θ is atomic follows from the definitions of *M* (i.e., the domain *d* and the interpretation function *I*) and the variable-assignment *s*. The other cases follow from the various clauses in the definition of satisfaction.

Since Γ ⊆ Γ″, we have that *M,s* satisfies every member of Γ. By Theorem 15, the restriction of *M* to the original language $\mathcal{L}1K$= and *s* also satisfies every member of Γ. Thus Γ is satisfiable.

A converse to Soundness (Theorem 18) is a straightforward corollary:

Theorem 21. For any formula θ and set Γ of formulas, if Γ⊨θ, then $\Gamma \vdash_D \theta$.

Proof: Suppose that Γ⊨θ. Then there is no interpretation *M* and assignment *s* such that *M,s* satisfies every member of Γ but does not satisfy θ. So the set Γ,¬θ is not satisfiable. By Completeness (Theorem 20), Γ,¬θ is inconsistent. So there is a formula ψ such that Γ,¬θ ⊢ ψ and Γ,¬θ ⊢ ¬ψ. By (¬I), Γ ⊢ ¬¬θ, and by (DNE) Γ ⊢ θ.

Our next item is a corollary of Theorem 9, Soundness (Theorem 18), and Completeness:

> **Corollary 22. Compactness.** A set Γ of formulas is satisfiable if and only if every finite subset of Γ is satisfiable.
>
> **Proof:** If M,s satisfies every member of Γ, then M,s satisfies every member of each finite subset of Γ. For the converse, suppose that Γ is not satisfiable. Then we show that some finite subset of Γ is not satisfiable. By Completeness (Theorem 20), Γ is inconsistent. By Theorem 9 (and Weakening), there is a finite subset $\Gamma' \subseteq \Gamma$ such that Γ' is inconsistent. By Corollary 19, Γ' is not satisfiable.

Soundness and completeness together entail that an argument is deducible if and only if it is valid, and a set of formulas is consistent if and only if it is satisfiable. So we can go back and forth between model-theoretic and proof-theoretic notions, transferring properties of one to the other. Compactness holds in the model theory because all derivations use only a finite number of premises.

Recall that in the proof of Completeness (Theorem 20), we made the simplifying assumption that the set K of non-logical constants is either finite or denumerably infinite. The interpretation we produced was itself either finite or denumerably infinite. Thus, we have the following:

> **Corollary 23. Löwenheim-Skolem Theorem.** Let Γ be a satisfiable set of sentences of the language $\mathcal{L}1K=$. If Γ is either finite or denumerably infinite, then Γ has a model whose domain is either finite or denumerably infinite.

In general, let Γ be a satisfiable set of sentences of $\mathcal{L}1K=$, and let κ be the larger of the size of Γ and denumerably infinite. Then Γ has a model whose domain is at most size κ.

There is a stronger version of Corollary 23. Let $M_1=<d_1,I_1>$ and $M_2=<d_2,I_2>$ be interpretations of the language $\mathcal{L}1K=$. Define M_1 to be a *submodel* of M_2 if $d_1 \subseteq d_2$, $I_1(c) = I_2(c)$ for each constant c, and I_1 is the restriction of I_2 to d_1. For example, if R is a binary relation letter in K, then for all a,b in d_1, the pair $<a,b>$ is in $I_1(R)$ if and only if $<a,b>$ is in $I_2(R)$. If we had included function letters among the non-logical terminology, we would also require that d_1 be closed under their interpretations in M_2. Notice that if M_1 is a submodel of M_2, then any variable-assignment on M_1 is also a variable-assignment on M_2.

Say that two interpretations $M_1=<d_1,I_1>$, $M_2=<d_2,I_2>$ are *elementarily equivalent* if one of them is a submodel of the other, and for any formula of the language and any variable-assignment s on the submodel, $M_1,s\models\theta$ if and only if $M_2,s\models\theta$. Notice that if two interpretations are elementarily equivalent, then they satisfy the same sentences.

> **Theorem 25. Downward Löwenheim-Skolem Theorem.** Let $M = <d,I>$ be an interpretation of the language $\mathcal{L}1K=$. Let d_1 be any subset of d, and let κ be the maximum of the size of K, the size of d_1, and denumerably infinite. Then there is a submodel $M' = <d$

$'$,I'> of M such that (1) d' is not larger than κ, and (2) M and M' are elementarily equivalent. In particular, if the set K of non-logical terminology is either finite or denumerably infinite, then any interpretation has an elementarily equivalent submodel whose domain is either finite or denumerably infinite.

Proof: Like completeness, this proof is complex, and we rest content with a sketch. The downward Löwenheim-Skolem theorem invokes the axiom of choice, and indeed, is equivalent to the axiom of choice. So let C be a choice function on the powerset of d, so that for each non-empty subset $e \subseteq d$, $C(e)$ is a member of e. We stipulate that if e is the empty set, then $C(e)$ is $C(d)$.

Let s be a variable-assignment on M, let θ be a formula of $\mathcal{L}1K$=, and let v be a variable. Define the *v-witness of θ over s*, written $w_v(\theta,s)$, as follows: Let q be the set of all elements $c \in d$ such that there is a variable-assignment s' on M that agrees with s on every variable except possibly v, such that $M,s' \vDash \theta$, and $s'(v)=c$. Then $w_v(\theta,s) = C(q)$. Notice that if $M,s \vDash \exists v\theta$, then q is the set of elements of the domain that can go for v in θ. Indeed, $M,s \vDash \exists v\theta$ if and only if q is non-empty. So if $M,s \vDash \exists v\theta$, then $w_v(\theta,s)$ (i.e., $C(q)$) is a chosen element of the domain that can go for v in θ. In a sense, it is a "witness" that verifies $M,s \vDash \exists v\theta$.

If e is a non-empty subset of the domain d, then define a variable-assignment s to be an *e-assignment* if for all variables u, $s(u)$ is in e. That is, s is an e-assignment if s assigns an element of e to each variable. Define $sk(e)$, the *Skolem-hull* of e, to be the set:

> $e \cup \{w_v(\theta,s) \mid \theta$ is a formula in $\mathcal{L}1K$=, v is a variable, and s is an e-assignment$\}$.

That is, the Skolem-Hull of e is the set e together with every v-witness of every formula over every e-assignment. Roughly, the idea is to start with e and then throw in enough elements to make each existentially quantified formula true. But we cannot rest content with the Skolem-hull, however. Once we throw the "witnesses" into the domain, we need to deal with $sk(e)$ assignments. In effect, we need a set which is its own Skolem-hull, and also contains the given subset d_1.

We define a sequence of non-empty sets $e_0, e_1, \ldots$ as follows: if the given subset d_1 of d is empty and there are no constants in K, then let e_0 be $C(d)$, the choice function applied to the entire domain; otherwise let e_0 be the union of d_1 and the denotations under I of the constants in K. For each natural number n, e_{n+1} is $sk(e_n)$. Finally, let d' be the union of the sets e_n, and let I' be the restriction of I to d'. Our interpretation is $M' = \langle d',I' \rangle$.

Clearly, d_1 is a subset of d', and so M' is a submodel of M. Let κ be the maximum of the size of K, the size of d_1, and denumerably infinite. A calculation reveals that the size of d' is at most κ, based on the fact that there are at most κ-many formulas, and thus, at most κ-many witnesses at each stage. Notice, incidentally, that this calculation relies on the fact that a denumerable union of sets of size at most κ is itself at most κ. This also relies on the axiom of choice.

The final item is to show that M' is elementarily equivalent to M: For every formula θ and every variable-assignment s on M',

$$M,s \vDash \theta \text{ if and only if } M',s \vDash \theta.$$

We proceed by induction on the complexity of θ. If θ is atomic, then the definition of satisfaction entails the equivalence. So let θ be non-atomic, and assume that $M,s \vDash \psi$ if and only if $M',s \vDash \psi$, for all assignments s on M' and all formulas ψ less complex than θ. Let s be any such assignment. If the main connective of θ is the negation sign or a binary connective, then the induction hypothesis entails that $M,s \vDash \theta$ if and only if $M',s \vDash \theta$. The remaining cases are those in which θ begins with a quantifier, i.e., θ is either $\exists v\psi$ or $\forall v\psi$. Suppose that $M',s \vDash \exists v\psi$. Then there is a variable-assignment s' that agrees with s except possibly at v such that $M',s' \vDash \psi$. By the induction hypothesis, $M,s' \vDash \psi$ and so $M,s \vDash \exists v\psi$. The converse is a bit tricky, and amounts to showing that the Skolem-hull of d' is d'. Assume that $M,s \vDash \exists v\psi$. We are given that s is a variable-assignment on d'. Since there are only finitely many free-variables in ψ, let n be any natural number such that for all variables u that occur free in ψ, $s(u)$ is in e_n. Let s_1 be an e_n-assignment that agrees with s on all of the free variables in ψ. Then, by Theorem 14, $M,s_1 \vDash \exists v\psi$. Let c be $w_v(\theta,s_1)$, the *v-witness of θ over s_1*. Notice that c is in e_{n+1} and so c is in d'. Let s_1' agree with s_1, except possibly at v, and let $s_1'(v)=c$. So s_1' is a variable-assignment on M'. By the definition of the witness function, $M,s_1' \vDash \psi$. By the induction hypothesis, $M',s_1' \vDash \psi$, and so $M',s_1 \vDash \exists v\psi$. By Theorem 14, $M',s \vDash \exists v\psi$. The final case, where θ has the form $\forall v\psi$, is similar.

Another corollary to Compactness (Corollary 22) is the opposite of the Löwenheim-Skolem theorem:

Theorem 26. Upward Löwenheim-Skolem Theorem. Let Γ be any set of formulas of $\mathcal{L}1K{=}$, such that for each natural number n, there is an interpretation $M_n = \langle d_n, I_n \rangle$, and an assignment s_n on M_n, such that d_n has at least n elements, and M_n,s_n satisfies every member of Γ. In other words, Γ is satisfiable and there is no finite upper bound to the size of the interpretations that satisfy every member of Γ. Then for any infinite cardinal κ, there is an interpretation $M=\langle d,I \rangle$ and assignment s on M, such that the size of d is *at least* κ and M,s satisfies every member of Γ. In particular, if Γ is a set of sentences, then it has arbitrarily

large models.

Proof: Add a collection of new constants $\{c\alpha \mid \alpha<\kappa\}$, of size κ, to the language, so that if c is a constant in K, then $c\alpha$ is different from c, and if $\alpha<\beta<\kappa$, then $c\alpha$ is a different constant than $c\beta$. Consider the set of formulas Γ' consisting of Γ together with the set $\{\neg c\alpha=c\beta \mid \alpha\neq\beta\}$. That is, Γ' consists of Γ together with statements to the effect that any two different new constants denote different objects. Let Γ'' be any finite subset of Γ', and let m be the number of new constants that occur in Γ''. Then expand the interpretation M_m to an interpretation M_m' of the new language, by interpreting each of the new constants in Γ'' as a different member of the domain d_m. By hypothesis, there are enough members of d_m to do this. One can interpret the other new constants at will. So M_m is a restriction of M_m'. By hypothesis (and Theorem 15), M'_m,s_m satisfies every member of Γ. Also M'_m,s_m satisfies the members of $\{\neg c\alpha=c\beta \mid \alpha\neq\beta\}$ that are in Γ''. So M'_m,s_m satisfies every member of Γ''. By compactness, there is an interpretation $M = \langle d,I\rangle$ and an assignment s on M such that M,s satisfies every member of Γ'. Since Γ' contains every member of $\{\neg c\alpha=c\beta \mid \alpha\neq\beta\}$, the domain d of M must be of size at least κ, since each of the new constants must have a different denotation. By Theorem 15, the restriction of M to the original language $\mathcal{L}1K=$ satisfies every member of Γ, with the variable-assignment s.

The proofs of the downward and upward Löwenheim-Skolem theorems can be combined to show that for any satisfiable set Γ of sentences, if there is no finite bound on the models of Γ, then for any infinite cardinal κ, there is a model of Γ whose domain has size *exactly* κ. Moreover, if M is any interpretation whose domain is infinite, then for any infinite cardinal κ, there is an interpretation M' whose domain has size exactly κ such that M and M' are elementarily equivalent.

These results indicate a weakness in the expressive resources of first-order languages like $\mathcal{L}1K=$. No satisfiable set of sentences can guarantee that its models are all denumerably infinite, nor can any satisfiable set of sentences guarantee that its models are uncountable. So in a sense, first-order languages cannot express the notion of "denumerably infinite", at least not in the model theory.

Let A be any set of sentences in a first-order language $\mathcal{L}1K=$, where K includes terminology for arithmetic, and assume that every member of A is true of the natural numbers. We can even let A be the set of all sentences in $\mathcal{L}1K=$ that are true of the natural numbers. Then A has uncountable models, indeed models of any infinite cardinality. Such interpretations are sometimes called *unintended*, or *non-standard* models of arithmetic. Let B be any set of first-order sentences that are true of the real numbers, and let C be any first-order axiomatization of set theory. Then if B and C are satisfiable (in infinite interpretations), then each of them has denumerably infinite models. That is, any first-order, satisfiable set theory or theory of the real numbers, has (unintended) models the size of the natural numbers. This is despite the fact that a sentence (seemingly) stating that the universe is uncountable is provable in most set-theories. This situation, known as the *Skolem paradox*, has generated much discussion, but we must refer the reader elsewhere for a sample of it.

Infinitary Logic

Traditionally, expressions in formal systems have been regarded as signifying finite inscriptions which are--at least in principle--capable of actually being written out in primitive notation. However, the fact that (first-order) formulas may be identified with natural numbers (via "Gödel numbering") and hence with finite *sets* makes it no longer necessary to regard formulas as inscriptions, and suggests the possibility of fashioning "languages" some of whose formulas--such as that in the above quotation--would be naturally identified as *infinite sets*. A "language" of this kind is called an *infinitary language*: in this article we discuss those infinitary languages which can be obtained in a straightforward manner from first-order languages by allowing conjunctions, disjunctions and, possibly, quantifier sequences, to be of infinite length. In the course of the discussion we shall see that, while the expressive power of such languages far exceeds that of their finitary (first-order) counterparts, very few of them possess the "attractive" features (e.g., compactness and completeness) of the latter. Accordingly, the infinitary languages that do in fact possess these features merit special attention.

In §1 we lay down the basic syntax and semantics of infinitary languages and demonstrate their expressive power by means of examples. §2 is devoted to those infinitary languages which permit only finite quantifier sequences: these languages turn out to be relatively well-behaved. In §3 we discuss the *compactness problem* for infinitary languages and its connection with purely set-theoretical questions concerning "large" cardinal numbers. In §4 an argument is sketched which shows that most "infinite quantifier" languages have a *second-order* nature and are, *ipso facto*, highly incomplete. In §5 we give a brief account of a certain special class of sublanguages of infinitary languages for which a satisfactory generalization of the compactness theorem can be proved. (This section links to a Supplement on the definition of admissible sets.) We conclude with historical and bibliographical remarks in §6.

1. Definition and Basic Properties of Infinitary Languages

Given a pair κ, λ of infinite cardinals such that $\lambda \leq \kappa$, we define a class of infinitary languages in each of which we may form conjunctions and disjunctions of sets of formulas of cardinality < κ, and quantifications over sequences of variables of length < λ.

Let $\mathcal{L}$ -- the (finitary) *base language* -- be an arbitrary but fixed first-order language with any number of extralogical symbols. The infinitary language $\mathcal{L}(\kappa, \lambda)$ has the following *basic symbols*:

- All symbols of $\mathcal{L}$
- A set **Var** of individual variables, where the cardinality of **Var** (written: |**Var**|) is λ
- A logical operator $\bigwedge$ (*infinitary conjunction*)

The class of *preformulas* of $\mathcal{L}(\kappa, \lambda)$ is defined recursively as follows:

- Each formula of $\mathcal{L}$ is a preformula;
- if φ and ψ are preformulas, so are $\varphi \wedge \psi$ and $\neg\varphi$;
- if Φ is a set of preformulas such that $|\Phi| < \kappa$, then $\bigwedge\Phi$ is a preformula;
- if φ is a preformula and $X \subseteq$ **Var** is such that $|X| < \lambda$, then $\exists X\varphi$ is a preformula;
- all preformulas are defined by the above clauses.

If Φ is a set of preformulas indexed by a set *I*, say $\Phi = \{\varphi_i : i \in I\}$, then we agree to write $\bigwedge\Phi$ for:

$$\bigwedge_{i \in I} \varphi$$

or, if *I* is the set of natural numbers, we write $\bigwedge\Phi$ for:

$$\varphi_0 \wedge \varphi_1 \wedge \ldots$$

If *X* is a set of individual variables indexed by an ordinal α, say $X = \{x_\xi : \xi < \alpha\}$, we agree to write $(\exists x_\xi)_{\xi<\alpha}\varphi$ for $\exists X\varphi$.

The logical operators $\vee$, $\rightarrow$, $\leftrightarrow$ are defined in the customary manner. We also introduce the operators $\bigvee$

(*infinitary disjunction*) and $\forall$ (*universal quantification*) by

$$\bigvee\Phi =_{df} \neg\bigwedge\{\neg\varphi : \varphi \in \Phi\}$$

$$\forall X\varphi =_{df} \neg\exists X\neg\varphi,$$

and employ similar conventions as for $\bigwedge$, $\exists$.

Thus $\mathcal{L}(\kappa,\lambda)$ is the infinitary language obtained from $\mathcal{L}$ by permitting conjunctions and disjunctions of length < κ and quantifications[1] of length < λ. Languages $\mathcal{L}(\kappa,\omega)$ are called *finite-quantifier* languages, the rest *infinite-quantifier* languages. Observe that $\mathcal{L}(\omega,\omega)$ is just $\mathcal{L}$ itself.

Notice the following *anomaly* which can arise in an infinitary language but not in a finitary one. In the language $\mathcal{L}(\omega_1,\omega)$, which allows countably infinite conjunctions but only finite quantifications, there are preformulas with so many free variables that they cannot be "closed" into sentences of $\mathcal{L}(\omega_1,\omega)$ by prefixing quantifiers. Such is the case, for example, for the $\mathcal{L}(\omega_1,\omega)$-preformula

$$x_0 < x_1 \wedge x_1 < x_2 \wedge \ldots \wedge x_n < x_{n+1} \ldots,$$

where $\mathcal{L}$ contains the binary relation symbol <. For this reason we make the following

> **Definition**. A *formula* of $\mathcal{L}(\kappa,\lambda)$ is a preformula which contains < λ free variables. The set of all formulas of $\mathcal{L}(\kappa,\lambda)$ will be denoted by **Form**($\mathcal{L}(\kappa,\lambda)$) or simply **Form**($\kappa,\lambda$) and the set of all sentences by **Sent**($\mathcal{L}(\kappa,\lambda)$) or simply **Sent**($\kappa,\lambda$).

In this connection, observe that, in general, nothing would be gained by considering "languages" $\mathcal{L}(\kappa,\lambda)$ with $\lambda > \kappa$. For example, in the "language" $\mathcal{L}(\omega,\omega_1)$, formulas will have only finitely many free variables, while there will be a host of "useless" quantifiers able to bind infinitely many free variables.[2]

Having defined the syntax of $\mathcal{L}(\kappa,\lambda)$, we next sketch its *semantics*. Since the extralogical symbols of $\mathcal{L}(\kappa,\lambda)$ are just those of $\mathcal{L}$, and it is these symbols which determine the form of the structures in which a given first-order language is to be interpreted, it is natural to define an $\mathcal{L}(\kappa,\lambda)$-structure to be simply an $\mathcal{L}$-structure. The notion of a formula of $\mathcal{L}(\kappa,\lambda)$ being *satisfied* in an $\mathcal{L}$-structure ***A*** (by a sequence of elements from the domain of ***A***) is defined in the same inductive manner as for formulas of $\mathcal{L}$ except that we must add two extra clauses corresponding to the clauses for $\bigwedge\Phi$ and $\exists X\varphi$ in the definition of preformula. In these two cases we naturally define:

> $\bigwedge\Phi$ is satisfied in ***A*** (by a given sequence) $\Leftrightarrow$ for all $\varphi \in \Phi$, φ is satisfied in ***A*** (by the sequence);

$\exists X\varphi$ is satisfied in $\boldsymbol{A} \Leftrightarrow$ there is a sequence of elements from the domain of $\boldsymbol{A}$ in bijective correspondence with X which satisfies φ in $\boldsymbol{A}$.

These informal definitions need to be tightened up in a rigorous development, but their meaning should be clear to the reader. Now the usual notions of *truth*, *validity*, *satisfiability*, and *model* for formulas and sentences of $\mathcal{L}(\kappa,\lambda)$ become available. In particular, if $\boldsymbol{A}$ is an $\mathcal{L}$-structure and $\sigma \in$ **Sent**(κ,λ), we shall write $\boldsymbol{A}\vDash\sigma$ for **A** is a model of σ, and $\vDash\sigma$ for σ *is valid*, that is, for all $\boldsymbol{A}$, $\boldsymbol{A}\vDash\sigma$. If $\Delta \subseteq$ **Sent**(κ,λ), we shall write $\Delta\vDash\sigma$ for σ *is a logical consequence of* Δ, that is, each model of Δ is a model of σ.

We now give some examples intended to display the expressive power of the infinitary languages $\mathcal{L}(\kappa, \lambda)$ with $\kappa \geq \omega_1$. In each case it is well-known that the notion in question cannot be expressed in any first-order language.

Characterization of the standard model of arithmetic in $\mathcal{L}(\omega_1,\omega)$. Here the *standard model of arithmetic* is the structure **N** = (N, +, ·, s, 0), where N is the set of natural numbers, +, ·, and 0 have their usual meanings, and s is the successor operation. Let $\mathcal{L}$ be the first-order language appropriate for **N**. Then the class of $\mathcal{L}$-structures isomorphic to **N** coincides with the class of models of the conjunction of the following $\mathcal{L}(\omega_1,\omega)$ sentences (where **0** is a name of 0):

$$\bigwedge_{m\in\omega}\ \bigwedge_{n\in\omega} s^m\mathbf{0} + s^n\mathbf{0} = s^{m+n}\mathbf{0}$$

$$\bigwedge_{m\in\omega}\ \bigwedge_{n\in\omega} s^m\mathbf{0} \cdot s^n\mathbf{0} = s^{m\cdot n}\mathbf{0}$$

$$\bigwedge_{m\in\omega}\ \bigwedge_{n\in\omega-\{m\}} s^m\mathbf{0} \neq s^n\mathbf{0}$$

$$\forall x \bigvee_{m\in\omega} x = s^m\mathbf{0}$$

The terms $s^n x$ are defined recursively by $s^0x = x$; $s^{n+1}x = s(s^nx)$.

Characterization of the class of all finite sets in $\mathcal{L}(\omega_1,\omega)$. Here the base language has no extralogical symbols. The class of all finite sets then coincides with the class of models of the $\mathcal{L}(\omega_1,\omega)$-sentence

$$\bigvee_{n\in\omega}\exists v_0 \ldots \exists v_n\forall x(x = v_0 \vee \ldots \vee x = v_n).$$

Truth definition in $\mathcal{L}(\omega_1,\omega)$ for a countable base language $\mathcal{L}$. Let $\mathcal{L}$ be a countable first-order language (for example, the language of arithmetic or set theory) which contains a name ***n*** for each natural number *n*, and let σ_0, σ_1, ... be an enumeration of its sentences. Then the $\mathcal{L}(\omega_1,\omega)$-formula

$$\mathbf{Tr}(x) =_{df} \bigvee_{n\in\omega} (x = \boldsymbol{n} \wedge \sigma_n)$$

is a *truth predicate* for $\mathcal{L}$ inasmuch as the sentence

$$\mathbf{Tr}(\boldsymbol{n}) \leftrightarrow \sigma_n$$

is valid for each *n*.

Characterization of well-orderings in $\mathcal{L}(\omega_1,\omega_1)$. The base language $\mathcal{L}$ here includes a binary predicate symbol $\preceq$. Let σ_1 be the usual $\mathcal{L}$-sentence characterizing linear orderings. Then the class of $\mathcal{L}$-structures in which the interpretation of $\preceq$ is a well-ordering coincides with the class of models of the $\mathcal{L}(\omega_1,\omega_1)$ sentence $\sigma = \sigma_1 \wedge \sigma_2$, where

$$\sigma_2 =_{df} \forall(v_n)_{n\in\omega}\, \exists x\, [\bigvee_{n\in\omega} (x = v_n) \wedge \bigwedge_{n\in\omega} (x \preceq v_n)].$$

Notice that the sentence σ_2 contains an *infinite quantifier*: it expresses the essentially *second-order* assertion that every countable subset has a least member. It can in fact be shown that the presence of this infinite quantifier is essential: the class of well-ordered structures cannot be characterized in any finite-quantifier language. This example indicates that infinite-quantifier languages such as $\mathcal{L}(\omega_1,\omega_1)$ behave rather like second-order languages; we shall see that they share the latters' defects (incompleteness) as well as some of their advantages (strong expressive power).

Many extensions of first-order languages can be *translated* into infinitary languages. For example, consider the generalized quantifier language $\mathcal{L}(Q_0)$ obtained from $\mathcal{L}$ by adding a new quantifier symbol Q_0 and interpreting $Q_0x\varphi(x)$ as *there exist infinitely many x such that* $\varphi(x)$. It is easily seen that the sentence $Q_0x\varphi(x)$ has the same models as the $\mathcal{L}(\omega_1,\omega)$-sentence

$$\neg\bigvee_{n\in\omega}\exists v_0\ldots\exists v_n\forall x[\varphi(x) \to (x = v_0 \vee \ldots \vee x = v_n)].$$

Thus $\mathcal{L}(Q_0)$ is, in a natural sense, translatable into $\mathcal{L}(\omega_1,\omega)$. Another language translatable into $\mathcal{L}(\omega_1,\omega)$ in this sense is the *weak second-order language* obtained by adding a countable set of monadic

predicate variables to $\mathcal{L}$ which are then interpreted as ranging over all *finite* sets of individuals.

2. Finite-Quantifier Languages

We have remarked that infinite-quantifier languages such as $\mathcal{L}(\omega_1,\omega_1)$ resemble second-order languages inasmuch as they allow quantification over infinite sets of individuals. The fact that this is not permitted in finite-quantifier languages suggests that these may be in certain respects closer to their first-order counterparts than might be evident at first sight. We shall see that this is indeed the case, notably in the case of $\mathcal{L}(\omega_1,\omega)$.

The language $\mathcal{L}(\omega_1,\omega)$ occupies a special place among infinitary languages because--like first-order languages--it admits an effective *deductive apparatus*. In fact, let us add to the usual first-order axioms and rules of inference the new axiom scheme

$$\bigwedge \Phi \rightarrow \varphi$$

for any countable set $\Phi \subseteq$ **Form**(ω_1,ω) and any $\varphi \in \Phi$, together with the new rule of inference

$$\frac{\varphi_0, \varphi_1, \ldots, \varphi_n, \ldots}{\bigwedge_{n\in\omega}\varphi_n}$$

and allow deductions to be of countable length. Writing $\vdash^*$ for deducibility in this sense, we then have the

$\mathcal{L}(\omega_1,\omega)$-**Completeness Theorem**. For any $\sigma \in$ **Sent**(ω_1,ω), $\models\sigma \Leftrightarrow \vdash^*\sigma$

As an immediate corollary we infer that this deductive apparatus is *adequate for deductions from countable sets of premises in* $\mathcal{L}(\omega_1,\omega)$. That is, with the obvious extension of notation, we have, for any *countable* set $\Delta \subseteq$ **Sent**(ω_1,ω)

(2.1) $\Delta\models\sigma \Leftrightarrow \Delta\vdash^*\sigma$

This completeness theorem can be proved by modifying the usual Henkin completeness proof for first-order logic, or by employing Boolean-algebraic methods. Similar arguments, applied to suitable further augmentations of the axioms and rules of inference, yield analogous completeness theorems for many other finite-quantifier languages.

If just deductions of countable length are admitted, then no deductive apparatus for $\mathcal{L}(\omega_1,\omega)$ can be set up which is adequate for deductions from *arbitrary* sets of premises, that is, for which (2.1) would hold for every set $\Delta \subseteq \mathbf{Sent}(\omega_1,\omega)$, *regardless of cardinality*. This follows from the simple observation that there is a first-order language $\mathcal{L}$ and an uncountable set Γ of $\mathcal{L}(\omega_1,\omega)$-sentences such that Γ *has no model but every countable subset of* Γ *does*. To see this, let $\mathcal{L}$ be the language of arithmetic augmented by ω_1 new constant symbols $\{\boldsymbol{c}_\xi : \xi < \omega_1\}$ and let Γ be the set of $\mathcal{L}(\omega_1,\omega)$-sentences $\{\sigma\} \cup \{\boldsymbol{c}_\xi \neq \boldsymbol{c}_\eta : \xi \neq \eta\}$, where σ is the $\mathcal{L}(\omega_1,\omega)$-sentence characterizing the standard model of arithmetic. This example also shows that the *compactness theorem* fails for $\mathcal{L}(\omega_1,\omega)$ and so also for any $\mathcal{L}(\kappa,\lambda)$ with $\kappa \geq \omega_1$.

Another result which holds in the first-order case but fails for $\mathcal{L}(\kappa,\omega)$ with $\kappa \geq \omega_1$ (and also for $\mathcal{L}(\omega_1, \omega_1)$, although this is more difficult to prove) is the *prenex normal form theorem*. A sentence is *prenex* if all its quantifiers appear at the front; we give an example of an $\mathcal{L}(\omega_1,\omega)$-sentence which is not equivalent to a conjunction of prenex sentences. Let $\mathcal{L}$ be the first-order language without extralogical symbols and let σ be the $\mathcal{L}(\omega_1,\omega)$-sentence which characterizes the class of finite sets. Suppose that σ were equivalent to a conjunction

$$\bigwedge_{i\in I} \sigma_i$$

of prenex $\mathcal{L}(\omega_1,\omega)$-sentences σ_i. Then each σ_i is of the form

$$Q_1x_1 \ldots Q_nx_n\, \varphi_i(x_1,\ldots, x_n),$$

where each Q_k is $\forall$ or $\exists$ and φ_i is a (possibly infinitary) conjunction or disjunction of formulas of the form $x_k = x_l$ or $x_k \neq x_l$. Since each σ_i is a sentence, there are only finitely many variables in each φ_i, and it is easy to see that each φ_i is then equivalent to a first-order formula. Accordingly each σ_i may be taken to be a first-order sentence. Since σ is assumed to be equivalent to the conjunction of the σ_i, it follows that σ and the set $\Delta = \{\sigma_i : i \in I\}$ have the same models. But obviously σ, and hence also Δ, have models of all finite cardinalities; the compactness theorem for sets of first-order sentences now implies that Δ, and hence also σ, has an infinite model, contradicting the definition of σ.

Turning to the *Löwenheim-Skolem theorem*, we find that the *downward* version has adequate generalizations to $\mathcal{L}(\omega_1,\omega)$ (and, indeed, to all infinitary languages). In fact, one can show in much the same way as for sets of first-order sentences that if $\Delta \subseteq \mathbf{Sent}(\omega_1,\omega)$ has an infinite model of cardinality $\geq |\Delta|$, it has a model of cardinality the larger of $\aleph_0$, $|\Delta|$. In particular, any $\mathcal{L}(\omega_1,\omega)$-sentence with an infinite model has a countable model.

On the other hand, the *upward* Löwenheim-Skolem theorem in its usual form *fails* for all infinitary languages. For example, the $\mathcal{L}(\omega_1,\omega)$-sentence characterizing the standard model of arithmetic has a

model of cardinality $\aleph_0$ but no models of any other cardinality. However, all is not lost here, as we shall see.

We define the *Hanf number* **h(L)** of a language L to be the least cardinal κ such that, if an **L**-sentence has a model of cardinality κ, it has models of arbitrarily large cardinality. The existence of **h(L)** is readily established. For each **L**-sentence σ not possessing models of arbitrarily large cardinality let $\kappa(\sigma)$ be the least cardinal κ such that σ does not have a model of cardinality κ. If λ is the supremum of all the $\kappa(\sigma)$, then, if a sentence of **L** has a model of cardinality λ, it has models of arbitrarily large cardinality.

Define the cardinals $\mu(\alpha)$ recursively by

$$\mu(0) = \aleph_0$$

$$\mu(\alpha+1) = 2^{\mu(\alpha)}$$

$$\mu(\lambda) = \sum_{\alpha<\lambda}\mu(\alpha) \text{ for limit } \lambda.$$

Then it can be shown that

$$\mathbf{h}(\mathcal{L}(\omega_1,\omega)) = \mu(\omega_1),$$

similar results holding for other finite-quantifier languages. The values of the Hanf numbers of infinite-quantifier languages such as $\mathcal{L}(\omega_1,\omega_1)$ are sensitive to the presence or otherwise of large cardinals, but must in any case greatly exceed that of $\mathcal{L}(\omega_1,\omega)$.

A result for $\mathcal{L}$ which generalizes to $\mathcal{L}(\omega_1,\omega)$ but to no other infinitary language is the

> **Craig Interpolation Theorem**: If $\sigma,\tau \in$ **Sent**(ω_1,ω) are such that $\models \sigma \rightarrow \tau$, then there is $\theta \in$ **Sent**(ω_1,ω) such that $\models \sigma \rightarrow \theta$ and $\models \theta \rightarrow \tau$, and each extralogical symbol occurring in θ occurs in both σ and τ.

The proof is a reasonably straightforward extension of the first-order case.

Finally, we mention one further result which generalizes nicely to $\mathcal{L}(\omega_1,\omega)$ but to no other infinitary language. It is well known that, if ***A*** is any finite $\mathcal{L}$-structure with only finitely many relations, there is an $\mathcal{L}$-sentence σ characterizing ***A*** up to isomorphism. For $\mathcal{L}(\omega_1,\omega)$ we have the following generalization known as

> **Scott's Isomorphism Theorem**. If ***A*** is a countable $\mathcal{L}$-structure with only countably many relations, then there is an $\mathcal{L}(\omega_1,\omega)$-sentence whose class of countable models coincides with the class of $\mathcal{L}$-structures isomorphic with ***A***.

The restriction to *countable* structures is essential because countability cannot in general be expressed by an $\mathcal{L}(\omega_1,\omega)$-sentence.

3. The Compactness Property

As we have seen, the compactness theorem in its usual form fails for all infinitary languages. Nevertheless, it is of some interest to determine whether infinitary languages satisfy some suitably modified version of the theorem. This so-called *compactness problem* turns out to have a natural connection with purely set-theoretic questions involving "large" cardinal numbers.

We construct the following definition. Let κ be an infinite cardinal. A language **L** is said to be *κ-compact* (resp. *weakly κ-compact*) if whenever Δ is a set of **L**-sentences (resp. a set of **L**-sentences of cardinality $\leq \kappa$) and each subset of Δ of cardinality $< \kappa$ has a model, so does Δ. Notice that the usual compactness theorem for $\mathcal{L}$ is precisely the assertion that $\mathcal{L}$ is ω-compact. One reason for according significance to the κ-compactness property is the following. Call L *κ-complete* (resp. *weakly κ-complete*) if there is a deductive system ***P*** for **L** with deductions of length $< \kappa$ such that, if Δ is a ***P***-consistent[3] set of **L**-sentences (resp. such that $|\Delta| \leq \kappa$), then Δ has a model. Observe that such a ***P*** will be adequate for deductions from arbitrary sets of premises (of cardinality $\leq \kappa$) in the sense of §2. It is easily seen that if **L** is κ-complete or weakly κ-complete, then **L** is κ-compact or weakly κ-compact. Thus, if we can show that a given language is *not* (weakly) κ-compact, then there can be no deductive system for it with deductions of length $< \kappa$ adequate for deductions from arbitrary sets of premises (of cardinality $\leq \kappa$).

It turns out, in fact, that most languages $\mathcal{L}(\kappa, \lambda)$ fail to be even weakly κ-compact, and, for those that are, κ must be an exceedingly *large* cardinal. We shall need some definitions.

An infinite cardinal κ is said to be *weakly inaccessible* if

> (a) $\lambda < \kappa \rightarrow \lambda^+ < \kappa$, (where λ^+ denotes the cardinal successor of λ), and
>
> (b) $|I| < \kappa$ and $\lambda_i < \kappa$ (for all $i \in I$) $\Rightarrow \sum_{i \in I} \lambda_i < \kappa$.

If in addition

> (c) $\lambda < \kappa \Rightarrow 2\lambda < \kappa$,

then κ is said to be (*strongly*) *inaccessible*. Since $\aleph_0$ is inaccessible, it is normal practice to confine attention to those inaccessible, or weakly inaccessible, cardinals that exceed $\aleph_0$. Accordingly, inaccessible or weakly inaccessible cardinals will always be taken to be *uncountable*. It is clear that such cardinals--if they exist--must be extremely large; and indeed the Gödel incompleteness theorem implies that the existence of even weakly inaccessible cardinals cannot be proved from the usual axioms of set theory.

Let us call a cardinal κ *compact* (resp. *weakly compact*) if the language $\mathcal{L}(\kappa,\lambda)$ is κ-compact (resp. weakly κ-compact). Then we have the following results:

> (3.1) $\aleph_0$ *is compact*. This is, of course, just a succinct way of expressing the compactness theorem for first-order languages.
>
> (3.2) κ is *weakly compact* $\Rightarrow$ $\mathcal{L}(\kappa,\omega)$ is *weakly* κ*-compact* $\Rightarrow$ κ is *weakly inaccessible*. Accordingly, it is consistent (with the usual axioms of set theory) to assume that no language $\mathcal{L}(\kappa,\omega)$ with $\kappa \geq \omega_1$ is weakly κ-compact, or, *a fortiori*, weakly κ-complete.
>
> (3.3) Suppose κ is inaccessible. Then κ is *weakly compact* $\Leftrightarrow$ $\mathcal{L}(\kappa,\omega)$ is *weakly* κ*-compact*. Also, Also κ is weakly compact $\Rightarrow$ *there is a set of* κ *inaccessibles before* κ. Thus a weakly compact inaccessible cardinal is exceedingly large; in particular it cannot be the first, second, ..., n^{th}, ... inaccessible.
>
> (3.4) κ *is compact* $\Rightarrow$ κ *is inaccessible*. (But, by the result immediately above, the converse fails.)

Let **Constr** stand for Gödel's axiom of constructibility; recall that **Constr** is consistent with the usual axioms of set theory.

> (3.5) *If* **Constr** *holds, then there are no compact cardinals*.
>
> (3.6) *Assume* **Constr** *and let* κ *be inaccessible. Then* κ *is weakly compact* $\Leftrightarrow$ $\mathcal{L}(\omega_1,\omega)$ *is weakly* κ*-compact for all* $\mathcal{L}$.
>
> (3.7) *If* **Constr** *holds, then there are no cardinals* κ *for which* $\mathcal{L}(\omega_1,\omega)$ *is compact*. Accordingly, it is consistent with the usual axioms of set theory to suppose that there is no cardinal κ such that all languages $\mathcal{L}(\omega_1,\omega)$ are κ-complete. This result is to be contrasted with the fact that *all* first-order languages are ω-complete.

The import of these results is that the compactness theorem fails very badly for most languages $\mathcal{L}(\kappa,\lambda)$

with $\kappa \geq \omega_1$.

Some historical remarks are in order here. In the 1930s mathematicians investigated various versions of the so-called *measure problem* for sets, a problem which arose in connection with the theory of Lebesgue measure on the continuum. In particular, the following very simple notion of measure was formulated. If X is a set, a (countably additive two-valued nontrivial) *measure* on X is a map μ on the power set $\mathbf{P}X$ to the set {0, 1} satisfying:

(a) $\mu(X) = 1$,

(b) $\mu(\{x\}) = \mu(\varnothing) = 0$ for all $x \in X$, and

(c) if $\boldsymbol{A}$ is any countable family of subsets of X, then $\mu(\bigcup \boldsymbol{A}) = \sum\{\mu(Y): Y \in \boldsymbol{A}\}$.

Obviously, whether a given set supports such a measure depends only on its cardinality, so it is natural to define a cardinal κ to be *measurable* if all sets of cardinality κ support a measure of this sort. It was quickly realized that a measurable cardinal must be inaccessible, but the falsity of the converse was not established until the 1960s when Tarski showed that measurable cardinals are weakly compact and his student Hanf showed that the first, second, etc. inaccessibles are not weakly compact (cf. (3.3)). Although the conclusion that measurable cardinals must be monstrously large is now normally proved without making the detour through weak compactness and infinitary languages, the fact remains that these ideas were used to establish the result in the first instance.

4. Incompleteness of Infinite-Quantifier Languages

Probably the most important result about first-order languages is the *Gödel completeness theorem* which of course says that the set of all valid formulas of any first-order language $\mathcal{L}$ can be generated from a simple set of axioms by means of a few straightforward rules of inference. A major consequence of this theorem is that, if the formulas of $\mathcal{L}$ are coded as natural numbers in some constructive way, then the set of (codes of) valid sentences is *recursively enumerable*. Thus, the completeness of a first-order language implies that the set of its valid sentences is *definable* in a particularly simple way. It would accordingly seem reasonable, given an *arbitrary* language **L**, to turn this implication around and suggest that, if the set of valid **L**-sentences is *not* definable in some simple fashion, then *no* meaningful completeness result can be established for **L**, or, as we shall say, that **L** is *incomplete*. In this section we are going to employ this suggestion in sketching a proof that "most" *infinite quantifier* languages are incomplete in this sense.

Let us first introduce the formal notion of *definability* as follows. If **L** is a language, $\boldsymbol{A}$ an **L**-structure, and X a subset of the domain A of $\boldsymbol{A}$, we say that X is *definable in* $\boldsymbol{A}$ by a formula $\varphi(x, y_1, \ldots, y_n)$ of **L** if there is a sequence $a_1, \ldots, a_n$ of elements of A such that X is the subset of all elements x A for which $\varphi(x, a_1, \ldots, a_n)$ holds in $\boldsymbol{A}$.

Now write *Val*(**L**) for the set of all the *valid* **L**-sentences, i.e., those that hold in every **L**-structure. In order to assign a meaning to the statement "*Val*(**L**) is definable", we have to specify

(i) a structure ***C*(L)**--the *coding structure* for **L**;

(ii) a particular one-one map--the *coding map*--of the set of formulas of **L** into the domain of ***C*(L)**.

Then, if we identify *Val*(**L**) with its image in ***C*(L)** under the coding map, we shall interpret the statement "*Val*(**L**) is definable" as the statement "*Val*(**L**), regarded as a subset of the domain of ***C*(L),** is definable in ***C*(L)** by a formula of **L**."

For example, when **L** is the first-order language $\mathcal{L}$ of arithmetic, Gödel originally used as coding structure the standard model of arithmetic $\mathbb{N}$ and as coding map the well-known function obtained from the prime factorization theorem for natural numbers. The recursive enumerability of *Val*($\mathcal{L}$) then means simply that the set of codes ("Gödel numbers") of members of *Val*($\mathcal{L}$) is definable in $\mathbb{N}$ by an $\mathcal{L}$-formula of the form $\exists y \varphi(x, y)$, where $\varphi(x, y)$ is a recursive formula.

Another, equivalent, coding structure for the first-order language of arithmetic is the structure[4] $<H(\omega), \in | H(\omega)>$ of *hereditarily finite sets*, where a set *x* is *hereditarily finite* if *x*, its members, its members of members, etc., are all finite. This coding structure takes account of the fact that first-order formulas are naturally regarded as finite sets.

Turning now to the case in which **L** is an infinitary language $\mathcal{L}(\kappa,\lambda)$, what would be a suitable coding structure in this case? We remarked at the beginning that infinitary languages were suggested by the possibility of thinking of formulas as set-theoretical objects, so let us try to obtain our coding structure by thinking about what kind of set-theoretical objects we should take infinitary formulas to be. Given the fact that, for each $\varphi \in$ **Form**(κ,λ), φ and its subformulas, subsubformulas, etc., are all of length $< \kappa$[5], a moment's reflection reveals that formulas of $\mathcal{L}(\kappa,\lambda)$ "correspond" to sets *x hereditarily of cardinality* $< \kappa$ in the sense that *x*, its members, its members of members, etc., are all of cardinality $< \kappa$. The collection of all such sets is written $H(\kappa)$. $H(\omega)$ is the collection of *hereditarily finite* sets introduced above, and $H(\omega_1)$ that of all *hereditarily countable* sets.

For simplicity let us suppose that the only extralogical symbol of the base language $\mathcal{L}$ is the binary predicate symbol $\underline{\in}$ (the discussion is easily extended to the case in which $\mathcal{L}$ contains additional extralogical symbols). Guided by the remarks above, as coding structure for $\mathcal{L}(\kappa,\lambda)$ we take the structure,

$$\mathcal{H}(\kappa) =_{df} <H(\kappa), \in | H(\kappa)>.$$

Now we can define the coding map of **Form**(κ,λ) into $\mathcal{H}(\kappa)$. First, to each basic symbol *s* of $\mathcal{L}(\kappa,\lambda)$

we assign a code object $\ulcorner s \urcorner \in H(\kappa)$ as follows. Let $\{v_\xi : \xi < \kappa\}$ be an enumeration of the individual variables of $\mathcal{L}(\kappa,\lambda)$.

Symbol	Code Object	Notation
$\neg$	1	$\ulcorner \neg \urcorner$
$\wedge$	2	$\ulcorner \wedge \urcorner$
$\bigwedge$	3	$\ulcorner \bigwedge \urcorner$
$\exists$	4	$\ulcorner \exists \urcorner$
$\in$	5	$\ulcorner \in \urcorner$
$=$	6	$\ulcorner = \urcorner$
v_ξ	$<0,\xi>$	$\ulcorner v_\xi \urcorner$

Then, to each $\varphi \in$ **Form**(κ,λ) we assign the code object $\ulcorner \varphi \urcorner$ recursively as follows:

$$\ulcorner v_\xi = v_\eta \urcorner =_{df} <\ulcorner v_\xi \urcorner, \ulcorner = \urcorner, \ulcorner v_\eta \urcorner>,$$

$$\ulcorner v_\xi \in v_\eta \urcorner =_{df} <\ulcorner v_\xi \urcorner, \ulcorner \in \urcorner, \ulcorner v_\eta \urcorner>;$$

for $\varphi, \psi \in$ **Form**(κ,λ),

$$\ulcorner \varphi \wedge \psi \urcorner =_{df} <\ulcorner \varphi \urcorner, \ulcorner \wedge \urcorner, \ulcorner \psi \urcorner>$$

$$\ulcorner \neg \varphi \urcorner =_{df} <\ulcorner \neg \urcorner, \ulcorner \varphi \urcorner>$$

$$\ulcorner \exists X \varphi \urcorner =_{df} <\ulcorner \exists \urcorner, \{\ulcorner x \urcorner : x \in X\}, \ulcorner \varphi \urcorner>;$$

and finally if $\Phi \subseteq$ **Form**(κ,λ) with $|\Phi| < \kappa$,

$$\ulcorner \bigwedge \varphi \urcorner =_{df} <\ulcorner \bigwedge \urcorner, \{\ulcorner \varphi \urcorner : \varphi \in \Phi\}>.$$

The map $\varphi \mapsto \ulcorner \varphi \urcorner$ from **Form**(κ,λ) into $H(\kappa)$ is easily seen to be one-one and is the required coding map. Accordingly, we agree to identify $Val(\mathcal{L}(\kappa,\lambda))$ with its image in $H(\kappa)$ under this coding map.

When is $Val(\mathcal{L}(\kappa,\lambda))$ a *definable* subset of $\mathcal{H}(\kappa)$? In order to answer this question we require the following definitions.

An $\mathcal{L}$-formula is called a Δ_0-*formula* if it is equivalent to a formula in which all quantifiers are of the

form $\forall x{\in}y$ or $\exists x{\in}y$ (i.e., $\forall x(x{\in}y \rightarrow ...)$ or $\exists x(x{\in}y \wedge ...)$). An $\mathcal{L}$-formula is a Σ_1-*formula* if it is equivalent to one which can be built up from atomic formulas and their negations using only the logical operators $\wedge$, $\vee$, $\forall x{\in}y$, $\exists x$. A subset X of a set A is said to be Δ_0 (resp. Σ_1) *on A* if it is definable in the structure $\langle A, \in | A\rangle$ by a Δ_0- (resp. Σ_1-) formula of $\mathcal{L}$.

For example, if we identify the set of natural numbers with the set $H(\omega)$ of hereditarily finite sets in the usual way, then for each $X \subseteq H(\omega)$ we have:

X is Δ_0 on $H(\omega) \Leftrightarrow X$ is recursive

X is Σ_1 on $H(\omega) \Leftrightarrow X$ is recursively enumerable.

Thus the notions of Δ_0- and Σ_1-set may be regarded as generalizations of the notions of *recursive* and *recursively enumerable* set, respectively.

The completeness theorem for $\mathcal{L}$ implies that $Val(\mathcal{L})$ -- regarded as a subset of $H(\omega)$ -- is recursively enumerable, and hence Σ_1 on $H(\omega)$. Similarly, the completeness theorem for $\mathcal{L}(\omega_1,\omega)$ (see §2) implies that $Val(\mathcal{L}(\omega_1,\omega))$ -- regarded as a subset of $H(\omega_1)$ -- is Σ_1 on $H(\omega_1)$. However, this pleasant state of affairs collapses completely as soon as $\mathcal{L}(\omega_1,\omega_1)$ is reached. For one can prove

Scott's Undefinability Theorem for $\mathcal{L}(\omega_1,\omega_1)$. *$Val(\mathcal{L}(\omega_1,\omega_1))$ is not definable in $\mathcal{H}(\omega_1)$ even by an $\mathcal{L}(\omega_1,\omega_1)$-formula*; *hence* a fortiori *$Val(\mathcal{L}(\omega_1,\omega_1))$ is not Σ_1 on $H(\omega_1)$.*

This theorem is proved in much the same way as the well-known result that the set of (codes of) valid sentences of the second-order language of arithemetic $\mathcal{L}^2$ is not second-order definable in its coding structure $\mathbb{N}$. To get this latter result, one first observes that $\mathbb{N}$ is characterized by a single $\mathcal{L}^2$-sentence, and then shows that, if the result were false, then "truth in $\mathbb{N}$" for $\mathcal{L}^2$-sentences would be definable by an $\mathcal{L}^2$-formula, thereby violating Tarski's theorem on the undefinability of truth.

Accordingly, to prove Scott's undefinability theorem along the above lines, one needs to establish:

(4.1) *Characterizability of the coding structure $\mathcal{H}(\omega_1)$ in $\mathcal{L}(\omega_1,\omega_1)$*: there is an $\mathcal{L}(\omega_1,\omega_1)$-sentence τ_0 such that, for all $\mathcal{L}$-structures $\boldsymbol{A}$,

$$\boldsymbol{A} \models \tau_0 \Leftrightarrow \boldsymbol{A} \cong \mathcal{H}(\omega_1).$$

(4.2) *Undefinability of truth for $\mathcal{L}(\omega_1,\omega_1)$-sentences in the coding structure*: there is no $\mathcal{L}(\omega_1,\omega_1)$-formula $\varphi(v_0)$ such that, for all $\mathcal{L}(\omega_1, \omega_1)$-sentences σ,

$$\mathcal{H}(\omega_1) \models \sigma \leftrightarrow \varphi(\ulcorner\sigma\urcorner).$$

(4.3) *There is a term* $t(v_0, v_1)$ *of* $\mathcal{L}(\omega_1,\omega_1)$ *such that, for each pair of sentences* σ, τ *of* $\mathcal{L}(\omega_1,\omega_1)$,

$$\mathcal{H}(\omega_1) \models t(\ulcorner\sigma\urcorner,\ulcorner\tau\urcorner) = \ulcorner\sigma \rightarrow \tau\urcorner.$$

(4.1) is proved by analyzing the set-theoretic definition of $\mathcal{H}(\omega_1)$ and showing that it can be "internally" formulated in $\mathcal{L}(\omega_1,\omega_1)$. (4.2) is established in much the same way as Tarski's theorem on the undefinability of truth for first- or second-order languages. (4.3) is obtained by formalizing the definition of the coding map $\sigma \mapsto \ulcorner\sigma\urcorner$ in $\mathcal{L}(\omega_1,\omega_1)$.

Armed with these facts, we can obtain Scott's undefinability theorem in the following way. Suppose it were false; then there would be an $\mathcal{L}(\omega_1,\omega_1)$-formula $\theta(v_0)$ such that, for all $\mathcal{L}(\omega_1,\omega_1)$-sentences σ,

(4.4) $\mathcal{H}(\omega_1) \models \theta(\ulcorner\sigma\urcorner) \Leftrightarrow \sigma \in Val(\mathcal{L}(\omega_1,\omega_1))$.

Let τ_0 be the sentence given in (4.1). Then we have, for all $\mathcal{L}(\omega_1,\omega_1)$-sentences σ,

$$\mathcal{H}(\omega_1) \models \sigma \Leftrightarrow \tau_0 \rightarrow \sigma \in Val(\mathcal{L}(\omega_1,\omega_1)),$$

so that, by (4.4),

$$\mathcal{H}(\omega_1) \models \sigma \Leftrightarrow \mathcal{H}(\omega_1) \models \theta(\ulcorner\tau_0 \rightarrow \sigma\urcorner).$$

If t is the term given in (4.3), it would follow that

$$\mathcal{H}(\omega_1) \models \sigma \leftrightarrow \theta(t(\ulcorner\tau_0\urcorner, \ulcorner\sigma\urcorner)).$$

Now write $\varphi(v_0)$ for the $\mathcal{L}(\omega_1,\omega_1)$-formula $\theta(t(\ulcorner\tau_0\urcorner, \ulcorner\sigma\urcorner))$. Then

$$\mathcal{H}(\omega_1) \models \sigma \leftrightarrow \varphi(\ulcorner\sigma\urcorner),$$

contradicting (4.2), and completing the proof.

Thus $Val(\mathcal{L}(\omega_1,\omega_1))$ is not definable *even by an* $\mathcal{L}(\omega_1,\omega_1)$*-formula*, so *a fortiori* $\mathcal{L}(\omega_1,\omega_1)$ is incomplete. Similar arguments show that Scott's undefinability theorem continues to hold when ω_1 is replaced by any successor cardinal κ^+; accordingly the languages $\mathcal{L}(\kappa^+,\kappa^+)$ are all incomplete.[6]

5. Sublanguages of $\mathcal{L}(\omega_1,\omega)$ and the Barwise Compactness Theorem

Given what we now know about infinitary languages, it would seem that $\mathcal{L}(\omega_1,\omega)$ is the only one to be reasonably well behaved. On the other hand, the failure of the compactness theorem to generalize to $\mathcal{L}(\omega_1,\omega)$ in any useful fashion is a severe drawback as far as applications are concerned. Let us attempt to analyze this failure in more detail.

Recall from §4 that we may code the formulas of a first-order language $\mathcal{L}$ as hereditarily finite sets, i.e., as members of $H(\omega)$. In that case each finite set of (codes of) $\mathcal{L}$-sentences is also a member of $H(\omega)$, and it follows that the compactness theorem for $\mathcal{L}$ can be stated in the form:

> (5.1) If $\Delta \subseteq$ **Sent**($\mathcal{L}$) is such that each subset $\Delta_0 \subseteq \Delta$, $\Delta_0 \in H(\omega)$ has a model, so does Δ.

Now it is well-known that (5.1) is an immediate consequence of the *generalized completeness theorem* for $\mathcal{L}$, which, stated in a form similar to that of (5.1), becomes the assertion:

> (5.2) If $\Delta \subseteq$ **Sent**($\mathcal{L}$) and $\sigma \in$ **Sent**($\mathcal{L}$) satisfy $\Delta \vDash \sigma$, then there is a deduction ***D*** of σ from Δ such that ***D*** $\in H(\omega)$.[7]

In §2 we remarked that the compactness theorem for $\mathcal{L}(\omega_1,\omega)$ fails very strongly; in fact, we constructed a set $\Gamma \subseteq$ **Sent**(ω_1,ω) such that

> (5.3) Each countable subset of Γ has a model but Γ does not.

Recall also that we introduced the notion of *deduction* in $\mathcal{L}(\omega_1,\omega)$; since such deductions are of countable length it quickly follows from (5.3) that

> (5.4) There is a sentence[8] $\sigma \in$ **Sent**(ω_1,ω) such that $\Gamma \vDash \sigma$, but there is no deduction of σ in $\mathcal{L}(\omega_1,\omega)$ from Γ.

Now the formulas of $\mathcal{L}(\omega_1, \omega)$ can be coded as members of $\mathcal{H}(\omega_1)$, and it is clear that $\mathcal{H}(\omega_1)$ is closed under the formation of countable subsets and sequences. Accordingly (5.3) and (5.4) may be written:

> (5.3 *bis*) Each $\Gamma_0 \subseteq \Gamma$ such that $\Gamma_0 \in \mathcal{H}(\omega_1)$ has a model, but Γ does not;

(5.4 *bis*) There is a sentence $\sigma \in \mathbf{Sent}(\omega_1,\omega)$ such that $\Gamma \models \sigma$, but there is no deduction $\boldsymbol{D} \in H(\omega_1)$ of σ from Γ.

It follows that (5.1) and (5.2) fail when "$\mathcal{L}$" is replaced by "$\mathcal{L}(\omega_1,\omega)$" and "$\mathcal{H}(\omega)$" by "$\mathcal{H}(\omega_1)$". Moreover, it can be shown that the set $\Gamma \subseteq \mathbf{Sent}(\omega_1,\omega)$ in (5.3 *bis*) and (5.4 *bis*) may be taken to be Σ_1 on $H(\omega_1)$. Thus the compactness and generalized completeness theorems fail even for Σ_1-sets of $\mathcal{L}(\omega_1, \omega)$-sentences.

We see from (5.4 *bis*) that the reason why the generalized completeness theorem fails for Σ_1-sets in $\mathcal{L}(\omega_1,\omega)$ is that, roughly speaking, $H(\omega_1)$ is not "closed" under the formation of deductions from Σ_1-sets of sentences in $H(\omega_1)$. So in order to remedy this it would seem natural to replace $H(\omega_1)$ by sets A which are, in some sense, closed under the formation of such deductions, and then to consider just those formulas whose codes are in A.

We now give a sketch of how this can be done.

First, we identify the symbols and formulas of $\mathcal{L}(\omega_1,\omega)$ with their codes in $H(\omega_1)$, as in §4. For each countable transitive[9] set A, let

$$\mathcal{L}_A = \mathbf{Form}(\mathcal{L}(\omega_1,\omega)) \cap A.$$

We say that $\mathcal{L}_A$ is a *sublanguage* of $\mathcal{L}(\omega_1,\omega)$ if the following conditions are satisfied:

(i) $\mathcal{L} \subseteq \mathcal{L}_A$

(ii) if $\varphi, \psi \in \mathcal{L}_A$, then $\varphi \wedge \psi \in \mathcal{L}_A$ and $\neg\varphi \in \mathcal{L}_A$

(iii) if $\varphi \in \mathcal{L}_A$ and $x \in A$, then $\exists x\varphi \in \mathcal{L}_A$

(iv) if $\varphi(x) \in \mathcal{L}_A$ and $y \in A$, then $\varphi(y) \in \mathcal{L}_A$

(v) if $\varphi \in \mathcal{L}_A$, every subformula of φ is in $\mathcal{L}_A$

(vi) if $\Phi \subseteq \mathcal{L}_A$ and $\Phi \in A$, then $\bigwedge\Phi \in \mathcal{L}_A$.

The notion of deduction in $\mathcal{L}_A$ is defined in the customary way; if Δ is a set of sentences of $\mathcal{L}_A$ and $\varphi \in \mathcal{L}_A$, then a *deduction* of φ from Δ in $\mathcal{L}_A$ is a deduction of φ from Δ in $\mathcal{L}(\omega_1, \omega)$ every formula of

which is in $\mathcal{L}_A$. We say that φ is *deducible* from Δ in $\mathcal{L}_A$ if there is a deduction $\boldsymbol{D}$ of φ from Δ in $\mathcal{L}_A$; under these conditions we write $\Delta \vdash_A \varphi$. In general, $\boldsymbol{D}$ will not be a member of A; in order to ensure that such a deduction can be found in A it will be necessary to impose further conditions on A.

Let A be a countable transitive set such that $\mathcal{L}_A$ is a sublanguage of $\mathcal{L}(\omega_1, \omega)$ and let Δ be a set of sentences of $\mathcal{L}_A$. We say that A (or, by abuse of terminology, $\mathcal{L}_A$) is Δ-*closed* if, for any formula φ of $\mathcal{L}_A$ such that $\Delta \vdash_A \varphi$, there is a deduction $\boldsymbol{D}$ of φ from Δ such that $\boldsymbol{D} \in A$. It can be shown that the only countable language which is Δ-closed for *arbitrary* Δ is the first-order language $\mathcal{L}$, i.e., when $A = H(\omega)$. However J. Barwise discovered that there are countable sets $A \subseteq H(\omega_1)$ whose corresponding languages $\mathcal{L}_A$ differ from $\mathcal{L}$and yet are Δ-closed *for all* Σ_1-*sets of sentences* Δ. Such sets A are called *admissible sets*; roughly speaking, they are extensions of the hereditarily finite sets in which recursion theory--and hence proof theory--are still possible.[10]

From Barwise's result one obtains immediately the

> **Barwise Compactness Theorem.** *Let* A *be a countable admissible set and let* Δ *be a set of sentences of* $\mathcal{L}_A$ *which is* Σ_1 *on* A. *If each* $\Delta' \subseteq \Delta$ *such that* $\Delta' \in$ A *has a model, then so does* Δ.

The presence of "Σ_1" here indicates that this theorem is a generalization of the compactness theorem for *recursively enumerable* sets of sentences.

Another version of the Barwise compactness theorem, useful for constructing models of set theory, is the following. Let **ZFC** be the usual set of axioms for Zermelo-Fraenkel set theory, including the axiom of choice. Then we have:

> **5.5. Theorem**. *Let A be a countable transitive set such that* $\boldsymbol{A} = \langle A, \in | A\rangle$ *is a model of* ***ZFC***. *If* Δ *is a set of sentences of* $\mathcal{L}_A$ *which is definable in* $\boldsymbol{A}$ *by a formula of the language of set theory and if each* $\Delta' \subseteq \Delta$ *such that* $\Delta' \in A$ *has a model, so does* Δ.

To conclude, we give a simple application of this theorem. Let $\boldsymbol{A} = \langle A, \in | A\rangle$ be a model of **ZFC**. A model $\boldsymbol{B} = \langle B, E\rangle$ of **ZFC** is said to be a *proper end-extension* of $\boldsymbol{A}$ if (i) $\boldsymbol{A} \subseteq \boldsymbol{B}$, (ii) $\boldsymbol{A} \neq \boldsymbol{B}$, (iii) $a \in A$, $b \in B$, $bEa \Rightarrow b \in A$. Thus a proper end-extension of a model of **ZFC** is a proper extension in which no "new" element comes "before" any "old" element. As our application of **5.5** we prove

> **5.6. Theorem**. *Each countable transitive model of* ***ZFC*** *has a proper end-extension.*

> **Proof**. Let $\boldsymbol{A} = \langle A, \in | A\rangle$ be a transitive model of **ZFC** and let $\mathcal{L}$ be the first-order language of set theory augmented by a name **a** for each $a \in A$, and an additional constant **c**. Let Δ be the set of $\mathcal{L}_A$-sentences comprising:

- all axioms of **ZFC**;
- $\mathbf{c} \neq \mathbf{a}$, for each $a \in A$;
- $\forall x(x \in \mathbf{a} \rightarrow \bigvee_{b \in a} x = \mathbf{b})$, for each $a \in A$;
- $\mathbf{a} \in \mathbf{b}$, for each $a \in b \in A$.

> It is easily shown that Δ is a subset of A which is definable in $\boldsymbol{A}$ by a formula of the language of set theory. Also, each subset $\Delta' \subseteq \Delta$ such that $\Delta' \in A$ has a model. For the set C of all $a \in A$ for which **a** occurs in Δ' belongs to A -- since Δ' does -- and so, if we interpret **c** as any member of the (necessarily nonempty) set A - C, then $\boldsymbol{A}$ is a model of Δ'. Accordingly, (5.5) implies that Δ has a model <*B*, *E*>. If we interpret each constant **a** as the element $a \in A$, then <*B*, *E*> is a proper end-extension of $\boldsymbol{A}$. The proof is complete.

The reader will quickly see that the first-order compactness theorem will not yield this result.

[Supplement: Definition of the Concept of Admissible Set

6. Historical and Bibliographical Remarks

§§**1** and **2**. Infinitary propositional and predicate languages seem to have made their first explicit appearance in print with the papers of Scott and Tarski [1958] and Tarski [1958]. The completeness theorem for $\mathcal{L}(\omega_1,\omega)$, as well as for other infinitary languages, was proved by Karp [1964]. The Hanf number calculations for $\mathcal{L}(\omega_1,\omega)$ were first performed by Morley [1965]. The nondefinability of well-orderings in finite-quantifier languages was proved by Karp [1965] and Lopez-Escobar [1966]. The interpolation theorem for $\mathcal{L}(\omega_1,\omega)$ was proved by Lopez-Escobar [1965] and Scott's isomorphism theorem for $\mathcal{L}(\omega_1,\omega)$ by Scott [1965].

§**3**. Results (3.2) and (3.3) are due to Hanf [1964], with some refinements by Lopez-Escobar [1966] and Dickmann [1975], while (3.4) was proved by Tarski. Result (3.5) is due to Scott [1961], (3.6) to Bell [1970] and [1972]; and (3.7) to Bell [1974]. Measurable cardinals were first considered by Ulam [1930] and Tarski [1939]. The fact that measurable cardinals are weakly compact was noted in Tarski [1962].

§**4**. The undecidability theorem for $\mathcal{L}(\omega_1,\omega_1)$ was proved by Scott in 1960; a fully detailed proof first appeared in Karp [1964]. The approach to the theorem adopted here is based on the account given in Dickmann [1975].

§**5**. The original motivation for the results presented in this section came from Kreisel; in his [1965] he pointed out that there were no compelling grounds for choosing infinitary formulas solely on the grounds of "length", and proposed instead that definability or "closure" criteria be employed. Kreisel's suggestion

was taken up with great success by Barwise [1967], where his compactness theorem was proved. The notion of admissible set is due to Platek [1966]. Theorem (5.6) is taken from Keisler [1974]. For further reading on the subject of infinitary languages, see Aczel [1973], Dickmann [1975], Karp [1964], Keisler [1974], and Makkai [1977].

Notes to Infinitary Logic

Notes

1. Observe, however, that while the formation rules for $\mathcal{L}(\kappa,\lambda)$ allow the deployment of infinitely many quantifiers, each preformula can contain only finitely many *alternations* of quantifiers. Languages permitting infinite quantifier alternations have been developed in the literature, but we shall not discuss them here.

2. This remark loses its force when the base language contains predicate symbols with infinitely many argument places. However, this possibility is excluded here since our base language is a conventional first-order language.

3. I.e., such that no contradictions can be derived from Δ using the deductive machinery in ***P***.

4. If *A* is a set, $\in | A$ denotes the membership relation on *A*, i.e., $\{<x, y> \in A \times A: x \in y\}$.

5. Strictly speaking, this is only the case when κ is *regular*, that is, not the limit of $< \kappa$ cardinals each of which is $< \kappa$. In view of the fact that "most" cardinals are regular, we shall take this as read.

6. It should be pointed out, however, that there are languages $\mathcal{L}(\kappa,\lambda)$ apart from $\mathcal{L}(\omega,\omega)$ and $\mathcal{L}(\omega_1,\omega)$ which are complete; for example, all languages $\mathcal{L}(\kappa^+,\omega)$ and $\mathcal{L}(\lambda,\lambda)$ with inaccessible λ.

7. This is just a consequence of the fact that a first-order deduction is a finite sequence, hence a member of $H(\omega)$.

8. Take σ to be any logically false sentence!

9. A set *A* is *transitive* if $x \in y \in A \Rightarrow x \in A$.

10. For the definition of admissible set, see the Supplement at the end of §5.

Definition of the Concept of Admissible Set

A nonempty transitive set A is said to be *admissible* when the following conditions are satisfied:

> (i) if $a, b \in A$, then $\{a, b\} \in A$ and $\bigcup A \in A$;
>
> (ii) if $a \in A$ and $X \subseteq A$ is Δ_0 on A, then $X \cap a \in A$;
>
> (iii) if $a \in A$, $X \subseteq A$ is Δ_0 on A, and $\forall x \in a \exists y (\langle x,y \rangle \in X)$, then, for some $b \in A$, $\forall x \in a \exists y \in b (\langle x,y \rangle \in X)$.

Condition (ii) -- the Δ_0-*separation scheme* -- is a restricted version of Zermelo's axiom of separation. Condition (iii) -- a similarly weakened version of the axiom of replacement -- may be called the Δ_0-*replacement scheme*.

It is quite easy to see that if A is a transitive set such that $\langle A, \in | A \rangle$ is a model of **ZFC**, then A is admissible. More generally, the result continues to hold when the power set axiom is omitted from **ZFC**, so that both $H(\omega)$ and $H(\omega_1)$ are admissible. However, since the latter is uncountable, the Barwise compactness theorem fails to apply to it.

Intuitionistic Logic

Intuitionistic logic encompasses the principles of logical reasoning which were used by L. E. J. Brouwer in developing his intuitionistic mathematics, beginning in [1907]. Because these principles also underly Russian recursive analysis and the constructive analysis of E. Bishop and his followers, intuitionistic logic may be considered the logical basis of constructive mathematics.

Philosophically, intuitionism differs from logicism by treating logic as a part of mathematics rather than as the foundation of mathematics; from finitism by allowing (constructive) reasoning about infinite collections; and from platonism by viewing mathematical objects as mental constructs with no independent ideal existence. Hilbert's formalist program, to justify classical mathematics by reducing it to a formal system whose consistency should be established by finitistic (hence constructive) means, was the most powerful contemporary rival to Brouwer's developing intuitionism. In his 1912 essay *Intuitionism and Formalism* Brouwer correctly predicted that any attempt to prove the consistency of complete induction on the natural numbers would lead to a vicious circle.

Brouwer rejected formalism *per se* but admitted the potential usefulness of formulating general logical principles expressing intuitionistically correct constructions, such as *modus ponens*. Formal systems for intuitionistic propositional and predicate logic were developed by Heyting [1930], Gentzen [1935] and Kleene [1952]. The Gödel-Gentzen negative translation interpreted classical predicate logic in its intuitionistic subsystem. In [1965] Kripke provided a semantics with respect to which intuitionistic predicate logic is complete.

Rejection of *Tertium Non Datur*

Intuitionistic logic can be succinctly described as classical logic without the Aristotelian law of excluded middle LEM (A ∨ ¬A), but with the law of contradiction (¬A → (A → B)). Brouwer [1908] observed that LEM was abstracted from finite situations, then extended without justification to statements about infinite collections. For example, if x, y range over the natural numbers 0, 1, 2, ... and B(x) abbreviates the property (there is a y > x such that both y and y+2 are prime numbers), then we have no general method for deciding whether B(x) is true or false for arbitrary x, so ∀x(B(x) ∨ ¬B(x)) cannot be asserted in the present state of our knowledge. And if A abbreviates the statement ∀xB(x), then (A ∨ ¬A) cannot be asserted because neither A nor (¬A) has yet been proved.

One may object that these examples depend on the fact that the Twin Primes Conjecture has not yet been settled. A number of Brouwer's original "counterexamples" depended on problems (such as Fermat's Last Theorem) which have since been solved. But to Brouwer the general LEM was equivalent to the *a priori* assumption that **every** mathematical problem has a solution -- an assumption he rejected, anticipating Gödel's incompleteness theorem by a quarter of a century.

Intuitionistic First-Order Predicate Logic

The Brouwer-Heyting-Kolmogorov explication of intuitionistic truth, outlined in Section 1 ("The Basis of Constructive Mathematics") of the article on Constructive Mathematics in this Encyclopedia, results in the constructive independence of the logical operations &, ∨, →, ∀, ∃. This contrasts with the classical situation, where e.g., (A ∨ B) is equivalent to ¬(¬A & ¬B), and ∃xA(x) is equivalent to ¬∀x¬A(x). Intuitionistically, a sentence of the form (A ∨ B) asserts that either a proof of A, or a proof of B, has been constructed; while ¬(¬A & ¬B) asserts that an algorithm has been constructed which would effectively convert any pair of constructions proving ¬A and ¬B respectively, into a proof of a known contradiction.

Following is a Hilbert-style formalism, from Kleene [1952], for intuitionistic first-order predicate logic. The language *L* has predicate letters P, Q(.),... of all arities, individual variables, and symbols for the logical operations. We use A, B, C as metavariables for well-formed formulas. There are three rules of inference:

- From A and (A → B), conclude B.
- From C and (C → A(x)), where x is a variable which does not occur free in C, conclude (C → ∀xA(x)).
- From C and (A(x) → C), where x is a variable which does not occur free in C, conclude (∃xA(x) → C).

The axioms are all formulas of the following forms, where in the last two schemas the subformula A(t) is

the result of substituting an occurrence of the term t for every free occurrence of x in A(x), and no variable free in t becomes bound in A(t) as a result of the substitution.

- A → (B → A).
- (A → B) → ((A → (B → C)) → (A → C)).
- A → (B → A & B).
- A & B → A.
- A & B → B.
- A → A ∨ B.
- B → A ∨ B.
- (A → C) → ((B → C) → (A ∨ B → C)).
- (A → B) → ((A → ¬B) → ¬A).
- ¬A → (A → B).
- ∀xA(x) → A(t).
- A(t) → ∃xA(x).

A *proof* is any sequence of formulas, each of which is an axiom or an immediate consequence, by a rule of inference, of preceding formulas of the sequence. Any proof is said to *prove* its last formula, which is called a *theorem* or *provable formula* of first-order intuitionistic predicate logic.

If, in the given list of axiom schemas, the law of contradiction:

- ¬A → (A → B).

is replaced by the law of double negation:

- ¬¬A → A.

(or, equivalently, by LEM), a formal system for classical first-order predicate logic results. Since the law of contradiction is a classical theorem, intuitionistic logic is contained in classical logic.

A Little Proof Theory

The Gödel-Gentzen negative translation associates with each formula A of the language *L* a formula *g*(A) with no ∨ or ∃, which is equivalent to A in classical predicate logic. We define *g*(A) by induction on the logical form of A, as follows:

- *g*(P) is ¬¬P, if P is prime.
- *g*(A & B) is (*g*(A) & *g*(B)).
- *g*(A ∨ B) is ¬(¬*g*(A) & ¬*g*(B)).
- *g*(A → B) is (*g*(A) → *g*(B)).

- $g(\neg A)$ is $\neg g(A)$.
- $g(\forall x A(x))$ is $\forall x\, g(A(x))$.
- $g(\exists x A(x))$ is $\neg\forall x \neg g(A(x))$.

For each formula A, *g*(A) is provable intuitionistically if and only if A is provable classically. In particular, if (B & ¬B) were classically provable for some formula B, then (*g*(B) & ¬*g*(B)) (which is *g*(B & ¬B)) would in turn be provable intuitionistically. Gödel [1933] interpreted these results as showing that intuitionistic logic is *richer* than classical logic, because

- intuitionistic logic distinguishes formulas which are classically equivalent, and
- intuitionistic logic is equiconsistent with classical logic.

Gödel extended the negative translation to number theory, but attempts to apply it to intuitionistic analysis failed because the negative translation of the countable axiom of choice has no intuitionistic justification.

Gödel [1932] observed that intuitionistic propositional logic has the *disjunction property*: If (A ∨ B) is a theorem, then A is a theorem or B is a theorem. Gentzen [1935] established the disjunction property for closed formulas of intuitionistic predicate logic. From this follows e.g., that (P ∨ ¬P) is not a theorem if P is prime. Kleene [1945, 1952] proved that intuitionistic first-order number theory also has the related (cf., Friedman [1975]) *existence property*: If ∃xA(x) is a closed theorem, then for some closed term t, A(t) is a theorem. Kleene and Friedman also proved existence properties for second-order intuitionistic systems.

Some Semantics

Intuitionistic systems have inspired a variety of interpretations, including Beth's tableaus, Rasiowa and Sikorski's topological models, and Kleene's recursive realizabilities. Kripke's [1965] possible-world semantics, with respect to which intuitionistic predicate logic is complete and consistent, most resembles classical model theory.

A *Kripke structure* **K** consists of a partially ordered set *K* of *nodes* and a *domain function D* assigning to each node *k* in *K* an inhabited set *D*(*k*) of constructive objects, such that if $k \le k'$, then $D(k) \subseteq D(k')$. In addition **K** has a *forcing* relation determined as follows.

For each node *k* let *L*(*k*) be the language extending *L* by new constants for all the elements of *D*(*k*). To each node *k* and each prime predicate P(x) assign a (possibly empty) subset *T*(P,*k*) of *D*(*k*) in such a way that if $k \le k'$ then $T(P,k) \subseteq T(P,k')$, and similarly for predicates of more variables. Say that *k forces* P(*d*) if and only if $d \in T(P,k)$. Now define forcing for compound sentences of *L*(*k*) by

- *k forces* (A & B) if *k forces* A and *k forces* B.

- k *forces* (A ∨ B) if k *forces* A or k *forces* B.
- k *forces* (A → B) if, for every $k' \geq k$, if k' *forces* A then k' *forces* B.
- k *forces* ¬A if for no $k' \geq k$ does k' *force* A.
- k *forces* ∀xA(x) if for every $k' \geq k$ and every $d \in D(k')$, k' *forces* A(d).
- k *forces* ∃xA(x) if for some $d \in D(k)$, k *forces* A(d).

Any such forcing relation is *consistent* and *monotone*:

- for no sentence A and no k does k force both A and ¬A.
- if $k \leq k'$ and k forces A then k' forces A.

Kripke's Soundness and Completeness Theorems establish that a sentence of L is provable in intuitionistic predicate logic if and only if it is forced by every node of every Kripke structure. Thus to show that (¬∀x¬P(x) → ∃xP(x)) is intuitionistically unprovable, it is enough to consider a Kripke structure with $K = \{k, k'\}$, $k < k'$, $D(k) = D(k') = \{0\}$, $T(\text{P},k)$ empty but $T(\text{P},k') = \{0\}$.

Additional Topics

While intuitionistic arithmetic is a proper part of classical arithmetic, the intuitionistic attitude toward mathematical objects results in a theory of real numbers diverging from the classical. For readers wishing to pursue this subject farther, the third edition [1971] of Heyting's classic [1956] is an authentic and accessible introduction to intuitionistic philosophy, logic and mathematical practice. Kleene and Vesley's [1965] provides a careful axiomatic treatment of, and a constructive consistency proof for, intuitionistic analysis. Troelstra and van Dalen's comprehensive [1988] brings the story nearly up to date.

Constructive Mathematics

Constructive mathematics is distinguished from its traditional counterpart, classical mathematics, by the strict interpretation of the phrase ‘there exists’ as ‘we can construct’. In order to work constructively, we need to re-interpret not only the existential quantifier but all the logical connectives and quantifiers as instructions on how to construct a proof of the statement involving these logical expressions.

Although certain individuals -- most notably Kronecker -- had expressed disapproval of the ‘idealistic’, nonconstructive methods used by some of their nineteenth century contemporaries, it is in the polemical writings of L.E.J. Brouwer (1881-1966), beginning with his Amsterdam doctoral thesis (Brouwer 1907) and continuing over the next forty-seven years, that the foundations of a precise, systematic approach to constructive mathematics were laid. In Brouwer's philosophy, known as intuitionism, mathematics is a free creation of the human mind, and an object exists if and only if it can be (mentally) constructed.

---

1. Introduction

Before mathematicians assert something they are supposed to have proved it true. What, then, do mathematicians mean when they assert a disjunction $P \vee Q$, where P and Q are syntactically correct statements in some (formal or informal) language that a mathematician can use? A natural -- although, as we shall see, not the unique -- interpretation of this disjunction is that not only does (at least) one of the statements P, Q hold, but also we can decide which one holds. Thus just as mathematicians will assert that P only when they have decided that P by proving it, they may assert $P \vee Q$ only when they either can decide -- that is, prove -- that P or decide (prove) that Q.

With this interpretation, however, mathematicians run into a serious problem in the special case where Q is the negation, $\neg P$, of P. To decide that $\neg P$ is to show that P implies a contradiction (such as 0=1). But it will often be that mathematicians have neither decided that P nor decided that $\neg P$. To see this, we need only reflect on the following:

> **Goldbach Conjecture**:
> Every even integer > 2 can be written as a sum of two primes,

which remains neither proved nor disproved despite the best efforts of many of the leading mathematicians since it was first raised in a letter from Goldbach to Euler in 1742. We are forced to conclude that, under the very natural interpretation of $P \vee Q$ just canvassed, only an optimist can retain a belief in the law of excluded middle, $P \vee \neg P$.

Traditional, or *classical*, mathematics gets round this by widening the interpretation of disjunction: it interprets $P \vee Q$ as $\neg(\neg P \wedge \neg Q)$, or in other words, "it is contradictory that both P and Q be false". In turn, this leads to the *idealistic* interpretation of existence, in which $\exists x P(x)$ means $\neg \forall x \neg P(x)$ ("it is contradictory that $P(x)$ be false for every x"). It is on these interpretations of disjunction and existence that mathematicians have built the grand, and apparently impregnable, edifice of classical mathematics which serves a foundation for the physical, the social, and (increasingly) the biological sciences. However, the wider interpretations come at a cost: for example, when we pass from our initial, natural interpretation of $P \vee Q$ to the unrestricted use of the idealistic one, $\neg(\neg P \wedge \neg Q)$, the resulting mathematics cannot generally be interpreted within computational models such as recursive function theory.

This point is illustrated by a well-worn example, the proposition:

> There exists irrational numbers a, b such that a^b is rational.

A slick classical proof goes as follows. Either $\sqrt{2}^{\sqrt{2}}$ is rational, in which case we take $a = b = \sqrt{2}$; or else $\sqrt{2}^{\sqrt{2}}$ is irrational, in which case we take $a = \sqrt{2}^{\sqrt{2}}$ and $b = \sqrt{2}$ (See Dummett 1977, 10). But as it stands, this proof does not enable us to pinpoint which of the two choices of the pair (a,b) has the required property. In order to determine the correct choice of (a,b), we would need to decide whether $\sqrt{2}^{\sqrt{2}}$ is rational or irrational, which is precisely to employ our initial interpretation of disjunction with P the statement "$\sqrt{2}^{\sqrt{2}}$ is rational".

Here is another illustration of the difference between interpretations. Consider the following simple statement about the set $\mathbb{R}$ of real numbers:

> (*) $\forall x \in \mathbb{R}\ (x = 0 \vee x \neq 0)$,

where, for reasons that we divulge shortly, $x \neq 0$ means that we can find a rational number r with $0 < r <$

|x|. A natural computational interpretation of (*) is that we have a procedure which, applied to any real number x, either tells us that x=0 or else tells us that $x \neq 0$. (For example, such a procedure might output 0 if x=0, and output 1 if $x \neq 0$.) However, because the computer can handle real numbers only by means finite rational approximations, we have the problem of *underflow*, in which a sufficiently small positive number can be misread as 0 by the computer; so there cannot be a decision procedure that justifies the statement (*). In other words, we cannot expect (*) to hold under our natural computational interpretation of the quantifier $\forall$ and the connective $\vee$.

Let's examine this from another angle. Let $G(n)$ act as shorthand for the statement “$2n + 2$ is a sum of two primes”, where n ranges over the positive integers, and define an infinite binary sequence **a** = $(a_1, a_2, \ldots)$ as follows:

$$a_n = \begin{cases} 0 \text{ if } G(n) \text{ holds for all } k \leq n \\ 1 \text{ if } \neg G(n) \text{ holds for some } k \leq n \end{cases}$$

There is no question that **a** is a computationally well-defined sequence, in the sense that we have an algorithm for computing a_n for each n: check the even numbers 4,6,8,…,$2n$+2 to determine whether each of them is a sum of two primes; in that case, set a_n=0; in the contrary case, set a_n=1. Now consider the real number whose n^{th} binary digit is a_n:

$$\begin{aligned} x &= (0 \cdot a_1 a_2 a_2 \cdots)_2 \\ &= 2^{-1}a_1 + 2^{-2}a_2 + \cdots \\ &= \sum_{n=1}^{\infty} 2^{-n}a_n. \end{aligned}$$

If (*) holds under our computational interpretation, then we can decide between the following two alternatives:

- $2^{-1}a_1 + 2^{-2}a_2 + \cdots = 0$, which implies that $a_n = 0$ for every n;
- we can find a positive integer N such that $2^{-1}a_1 + 2^{-2}a_2 + \cdots > 2^{-N}$.

In the latter case, by testing $a_1,\ldots,a_N$, we can find $n \leq N$ such that $a_n = 1$. Thus the computational interpretation of (*) enables us to decide whether there exists n such that $a_n = 1$; in other words, it enables us to decide the status of the Goldbach Conjecture.

The use of the Goldbach Conjecture here is purely dramatic. To avoid it, we define a function f on the set of binary sequences as follows:

$$f(a) = \begin{cases} 0 \text{ if } a_n = 0 \text{ for all } n \\ 1 \text{ if } a_n = 1 \text{ for some } n. \end{cases}$$

The argument of the preceding paragraph can then be modified to show that, under our computational interpretation, (*) provides us with a procedure for calculating *f*(*a*) for any computationally well-defined binary sequence *f*(*a*). Now, the computability of the function *f* can be expressed informally by the following:

> **Limited Principle of Omniscience (LPO)**:
> For each binary sequence $(a_1,a_2,\ldots)$ either $a_n = 0$ for all n or else there exists n such that $a_n = 1$,

which is generally regarded as an essentially nonconstructive principle, for several reasons. First, its recursive interpretation,

> There is a recursive algorithm which, applied to any recursively defined binary sequence $(a_1,a_2,\ldots)$, outputs 0 if $a_n = 0$ for all n, and outputs 1 if $a_n = 1$ for some n,

is provably false within recursive function theory, even with classical logic (see Bridges & Richman 1987, Chapter 3); so if we want to allow a recursive interpretation of all our mathematics, then we cannot use LPO. Secondly, there is a model theory (involving the use of Kripke models) in which it can be shown that LPO is not derivable in Peano arithmetic using the computational interpretation of the connectives and quantifiers that we state in more detail in the next section (Bridges & Richman 1987, Chapter 7).

2. Constructive Interpretation of Logic

It should, by now, be clear that a full-blooded computational development of mathematics disallows the idealistic interpretations of disjunction and existence upon which most classical mathematics depends. In fact, in order to work constructively, we need to return from the classical interpretations back to the natural, constructive ones, as follows.

$\vee$ (or):	to prove $P \vee Q$ we must have either a proof of P or a proof of Q.
$\wedge$ (and):	to prove $P \wedge Q$ we must have a proof of P and a proof of Q.
$\Rightarrow$ (implies):	a proof of $P \Rightarrow Q$ is an algorithm that converts a proof of P into a proof of Q.
$\neg$ (not):	to prove $\neg P$ we must show that P implies $0 = 1$.
$\exists$ (there exists):	to prove $\exists x P(x)$ we must construct an object x and prove that $P(x)$ holds.

$\forall$ (for each/all): a proof of $\forall x P(x)$ is an algorithm that, applied to any object x, proves that $P(x)$ holds.

These computational interpretations can be made more precise using Kleene's notion of *realizability*; see (Dummett 1977, 318-335; Beeson 1985, Chapter VII).

Why would we want to do this? First, there is the desire to retain, as far as possible, computational interpretations of our mathematics. Ideally, we are trying to develop mathematics in such a way that if a theorem asserts the existence of an object x with a property P, then the proof of the theorem embodies algorithms for constructing x and for demonstrating, by whatever calculations are necessary, that x has the property P. Here are some examples of theorems, each followed by an informal description of the requirements for its constructive proof.

(A) For each real number x, either $x = 0$ or $x \neq 0$.

Proof requirement: An algorithm which, applied to a given real number x, would decide whether $x = 0$ or $x \neq 0$. Note that, in order to make this decision, the algorithm might use not only the data describing x but also the data showing that x is actually a real number.

(B) Each nonempty subset S of *R that is bounded above has a least upper bound.*

Proof requirement: An algorithm which, applied to a set S of real numbers, a member s of S, and an upper bound for S,

i. computes an object b and shows that b is a real number;
ii. shows that $x \leq b$ for each $x \in$ S; and
iii. given a real number $b' < b$, computes an element x of S such that $x > b'$.

(C) If f is a continuous real-valued mapping on the closed interval [0,1] such that $f(0)f(1) < 0$, then there exists x such that $0 < x < 1$ and $f(x) = 0$.

Proof requirement: An algorithm which, applied to the function f, a modulus of continuity for f, and the values $f(0)$ and $f(1)$,

i. computes an object x and shows that x is a real number between 0 and 1, and
ii. shows that $f(x) = 0$.

(D) If f is a continuous real-valued mapping on the closed interval [0,1] such that $f(0)f(1) < 0$, then for each $\varepsilon > 0$ there exists x such that $0 < x < 1$ and $|f(x)| < \varepsilon$.

Proof requirement: An algorithm which, applied to the function f, a modulus of continuity for f, the values $f(0)$ and $f(1)$, and a positive number ε,

i. computes an object x and shows that x is a real number between 0 and 1, and
ii. shows that $|f(x)| < \varepsilon$.

We already have reasons for doubting that (A) has a constructive proof. If the proof requirements for (B) can be fulfilled, then, given a binary sequence $(a_1,a_2,\ldots)$, we can apply our proof of (B) to the set $\{a_1,a_2,\ldots\}$ in order to determine its supremum σ. Computing σ with an error < 1/2, we then determine whether $\sigma = 0$ or $\sigma = 1$; in the first case, $a_n = 0$ for all n, whereas in the second, we can easily find N such that $a_N = 1$. Thus (B) implies LPO and is therefore essentially nonconstructive. However, in Bishop's constructive theory of the real numbers, based on Cauchy sequences with a preassigned convergence rate, we can prove the following:

> **Constructive Least-Upper-Bound Principle**:
> Let S be a nonempty subset of R that is bounded above. Then S has a least upper bound if and only if it is *located*, in the sense that for all real numbers α, β with $\alpha < \beta$, either β is an upper bound for S or else there exists x in> S with $x > \alpha$ (Bishop & Bridges 1985, p. 37, Proposition (4.3))

Each of statements (C) and (D), which are classically equivalent, is a version of the Intermediate Value Theorem. In these statements, a *modulus of continuity* for f is a set Ω of ordered pairs (ε, δ) of positive real numbers with the following two properties:

- for each $\varepsilon > 0$ there exists $\delta > 0$ such that $(\varepsilon, \delta) \in \Omega$;
- for each $(\varepsilon, \delta) \in \Omega$, and for all $x,y \in [0,1]$ such that $|x - y| < \delta$, we have $|f(x) - f(y)| < \varepsilon$.

Statement (C) is essentially nonconstructive, since it entails the following nonconstructive principle:

> **Lesser Limited Principle of Omniscience (LLPO)**:
> For each binary sequence $(a_1,a_2,\ldots)$ with at most one term equal to 1, either $a_n = 0$ for all even n or else $a_n = 0$ for all odd n.

Statement (D), a weak form of (C), can be proved constructively, using an interval-halving argument of a standard type. The following stronger constructive intermediate value theorem, which suffices for most practical purposes, is proved using an approximate interval-halving argument:

> Let f be a continuous real-valued mapping on the closed interval [0,1] such that $f(0)$ and $f(1)$ have opposite signs. Suppose also that f is *locally nonzero*, in the sense that for each x

$\in$ [0,1] and each $r > 0$, there exists y such that $|x - y| < r$ and $f(y) \neq 0$. Then there exists x such that $0 < x < 1$ and $f(x)=0$.

The situation of the intermediate value theorem is typical of many in constructive analysis, where we find one classical theorem with several constructive versions, some or all of which may be equivalent under classical logic. (See also, for example, Bridges *et al*. 1982.)

There is one omniscience principle whose constructive status is less clear than that of LPO and LLPO, namely, the following:

Markov's Principle (MP):
For each binary sequence (a_n), if it is contradictory that all the terms a_n equal 0, then there exists a term equal to 1.

This principle is equivalent to a number of simple classical propositions, including the following:

- For each real number x, if it is contradictory that x equal 0, then $x \neq 0$ (in the sense we mentioned earlier).
- For each real number x, if it is contradictory that x equal 0, then there exists $y \in \mathbb{R}$ such that $xy = 1$.
- For each one-one continuous mapping $f : [0,1] \to \mathbb{R}$, if $x \neq y$, then $f(x) \neq f(y)$.

Markov's Principle represents an unbounded search: if you have a proof that all terms a_n being 0 leads to a contradiction, then, by testing the terms $a_1,a_2,a_3,\ldots$ in turn, you are 'guaranteed' to come across a term equal to 1; but this guarantee does not extend to an assurance that you will find the desired term before the end of the universe. Most practitioners of constructive mathematics view Markov's Principle with at least suspicion, if not downright disbelief. Such views are reinforced by the observation that there is a Kripke Model showing that MP is not derivable in Peano arithmetic under our computational interpretation of logic. (See Bridges & Richman 1987, 137-138.)

3. Varieties of Constructive Mathematics

The desire to retain the possibility of a computational interpretation is one motivation for using the constructive reinterpretations of the logical connective and quantifiers that we gave above; but it is not exactly the motivation of the pioneers of constructivism in mathematics.

In the late nineteenth century, certain individuals -- most notably Kronecker and Poincaré -- had expressed doubts, or even disapproval, of the idealistic, nonconstructive methods used by some of their contemporaries; but it is in the polemical writings of L.E.J. Brouwer (1881-1966), beginning with his Amsterdam doctoral thesis in 1907 and continuing over the next forty-seven years, that the foundations of a precise, systematic approach to constructive mathematics were laid. In Brouwer's philosophy, known

as *intuitionism*, mathematics is a free creation of the human mind, and an object exists if and only if it can be (mentally) constructed. If one takes that philosophical stance, then one is inexorably drawn to the foregoing constructive interpretation of the logical connectives and quantifiers: for how could a proof of the impossibility of the non-existence of a certain object x -- an idealistic proof of the existence of x -- describe a mental construction of x? Brouwer was not the clearest expositor of his ideas, as is shown by the following quotation:

> Mathematics arises when the subject of two-ness, which results from the passage of time, is abstracted from all special occurrences. The remaining empty form [the relation of n to n+1] of the common content of all these two-nesses becomes the original intuition of mathematics and repeated unlimitedly creates new mathematical subjects. (quoted in Kline 1972, pp. 1199-2000)

A modern precis of Brouwer's view was given by Errett Bishop (Bishop 1967, p. 2):

> The primary concern of mathematics is number, and this means the positive integers. We feel about number the way Kant felt about space. The positive integers and their arithmetic are presupposed by the very nature of our intelligence and, we are tempted to believe, by the very nature of intelligence in general. The development of the positive integers from the primitive concept of the unit, the concept of adjoining a unit, and the process of mathematical induction carries complete conviction. In the words of Kronecker, the positive integers were created by God.

However obscure Brouwer's writings could be, one thing was always clear: for him, mathematics took precedence over logic. One might say, as Hermann Weyl does in the following passage, that Brouwer saw classical mathematics as flawed precisely in its use of classical logic without reference to the underlying mathematics:

> According to [Brouwer's] view and reading of history, classical logic was abstracted from the mathematics of finite sets and their subsets. ... Forgetful of this limited origin, one afterwards mistook that logic for something above and prior to all mathematics, and finally applied it, without justification, to the mathematics of infinite sets. This is the Fall and original sin of set theory, for which it is justly punished by the antinomies. It is not that such contradictions showed up that is surprising, but that they showed up at such a late stage of the game. (quoted in Kline 1972, p. 2001)

In particular, this misuse of logic led to nonconstructive existence proofs which, in Hermann Weyl's words, “inform the world that a treasure exists without disclosing its location”.

In order to describe the logic used by the intuitionist mathematician, it was necessary first to analyse the mathematical processes of the mind, from which analysis the logic could be extracted. In 1930, Brouwer's most famous pupil, Arend Heyting, published a set of formal axioms which so clearly

characterise the logic used by the intuitionist that they have become universally known as the axioms for intuitionistic logic (Heyting 1930). These axioms captured the informal computational interpretations of the connectives and quantifiers that we gave earlier. Over the years, Brouwer added principles, suggested by his introspective analysis of the nature of the continuum, which made intuitionistic mathematics diverge dramatically from its classical counterpart. The reader is referred to the entry on intuitionistic logic for more information about such matters.

Unfortunately -- and perhaps inevitably, in the face of opposition from mathematicians of such stature as Hilbert -- Brouwer's intuitionist school of mathematics and philosophy became more and more involved in what, at least to classical mathematicians, appeared to be quasi-mystical speculation about the nature of constructive thought, to the detriment of the practice of constructive mathematics itself. On the other hand, in the late 1940s the Russian mathematician A.A. Markov (Markov 1954) began the development of a form of recursive constructive mathematics (RUSS), which was, essentially, recursive function theory with intuitionistic logic (see Kushner 1985). In this variety the objects are defined by means of Gödel-numberings, and the procedures are all recursive; the main distinction between RUSS and the classical recursive analysis developed after, in 1936, the work of Turing, Church, and others clarified the nature of computable processes, is that the logic used in RUSS is intuitionistic. Thus RUSS may be described as ‘recursive mathematics with intuitionistic logic’.

One obstacle faced by the mathematician attempting to come to grips with RUSS is that, expressed in the language of recursion theory, it is not easily readable; indeed, on opening a page of Kushner's excellent lectures, one might be forgiven for wondering whether this is analysis or logic. Fortunately, one can get to the heart of RUSS by an axiomatic approach, as shown in Richman 1983.

Progress in all varieties of constructive mathematics was relatively slow throughout the next decade and a half. What was needed to raise the profile of constructivism in mathematics was a top-ranking classical mathematician to show that a thoroughgoing constructive development of mathematics was possible without a commitment to Brouwer's non-classical principles or to the machinery of recursive function theory. This need was fulfilled in 1967, with the appearance of Errett Bishop's monograph *Foundations of Constructive Analysis* (Bishop 1967), the product of an astonishing couple of years in which, working in the informal but rigorous style used by normal analysts, Bishop provided a constructive development of a large part of twentieth-century analysis, including the Stone-Weierstrass Theorem, the Hahn-Banach and separation theorems, the spectral theorem for self-adjoint operators on a Hilbert space, the Lebesgue convergence theorems for abstract integrals, Haar measure and the abstract Fourier transform, ergodic theorems, and the elements of Banach algebra theory. (See also Bishop & Bridges 1985.) Thus, at a stroke, he gave the lie to the commonly-held view expressed so forcefully by Hilbert:

> Taking the principle of excluded middle from the mathematician would be the same, say, as proscribing the telescope to the astronomer or to the boxer the use of his fists. (Hilbert 1928)

Not only did Bishop's mathematics (BISH) have the advantage of readability -- if you open Bishop's

book at any page, what you see is clearly recognisable as analysis, even if, from time to time, his moves in the course of a proof may appear strange to one schooled in the use of the law of excluded middle -- but, unlike intuitionistic or recursive mathematics, it admits many different interpretations. Intuitionistic mathematics, Markov's recursive constructive mathematics, and even classical mathematics all provide models of BISH. In fact, the results and proofs in BISH can be interpreted, with at most minor amendments, in any reasonable model of computable mathematics, such as, for example, Weihrauch's Type Two Effectivity Theory (Weihrauch 1996, 2000).

How is this multiple interpretability achieved? At least in part by Bishop's refusal to pin down his primitive notion of ‘algorithm’ or, in his words, ‘finite routine’. This refusal has led to the criticism that his approach lacks the precision that a logician would normally expect of a foundational system. However, this criticism can be overcome by looking more closely at what practitioners of BISH actually do, as distinct from what Bishop may have thought he was doing, when they prove theorems: in practice, they are doing *mathematics with intuitionistic logic*. Experience shows that the restriction to intuitionistic logic always forces mathematicians to work in a manner that, at least informally, can be described as algorithmic; so *algorithmic mathematics appears to be equivalent to mathematics that uses only intuitionistic logic*. If that is the case, then we can practice constructive mathematics using intuitionistic logic on any reasonably defined mathematical objects, not just some class of ‘constructive objects’.

This view, more or less, appears to have first been put forward by Richman (1990, 1996). Taking the logic as the primary characteristic of constructive mathematics, it does not reflect the primacy of mathematics over logic that was part of the belief of Brouwer, Heyting, Markov, Bishop, and other pioneers of constructivism. On the other hand, it does capture the essence of constructive mathematics in practice.

Thus one might distinguish between the *ontological constructivism* of Brouwer and others who are led to constructive mathematics through a belief that mathematical objects are mental creations, and the *epistemological constructivism* of Richman and those who see constructive mathematics as characterised by its methodology, based on the use of intuitionistic logic. Of course, the former approach to constructivism inevitably leads to the latter; and the latter is certainly not inconsistent with a Brouwerian ontology.

4. Conclusion

From a technical point of view, there seem to be (at least) two ways of handling the computational content and interpretation of mathematics. One way uses classical logic. In order to avoid decisions, such as whether or not a real number equals 0, that cannot be made by a real computer, one then has to work within a carefully specified algorithmic framework such as that of recursive function theory. The second approach uses intuitionistic logic, which automatically takes care of computationally inadmissible decisions. It is then unnecessary to insist upon a closely circumscribed algorithmic framework, so one can work in the style of an analyst, algebraist, geometer, ... , the only constraints being those imposed by intuitionistic logic.

Inconsistent Mathematics

Inconsistent mathematics is the study of the mathematical theories that result when classical mathematical axioms are asserted within the framework of a (non-classical) logic which can tolerate the presence of a contradiction without turning every sentence into a theorem.

Inconsistent Mathematics

Inconsistent Mathematics began historically with foundational considerations. Set-theoretic paradoxes such as Russell's led to attempts to produce a consistent set theory as a foundation for mathematics. But, as is well known, set theories such as ZF, NBG and the like were in various ways ad hoc. Hence, a number of people including da Costa (1974), Brady (1971), Priest, Routley, and Norman (1989), considered it preferable to retain the full power of the natural abstraction principle (every predicate determines a set), and tolerate a degree of inconsistency in set theory. This requires, of course, that one dispense with the logical principle *ex contradictione quodlibet* (ECQ) (from a contradiction every proposition may be deduced), as well as any principle which leads to it, such as disjunctive syllogism (DS) (from *A*-or-*B* and not-*A* deduce *B*). But considerable debate, in Burgess (1981) and Mortensen (1983), made it clear that dispensing with ECQ and DS was not so counter-intuitive, especially when a plausible story emerged about the special conditions under which they continue to hold.

In addition, mathematics has a metalanguage; that is, names for mathematical statements and other parts of syntax, self-reference, proof and truth. Gödel's contribution to the philosophy of mathematics was to show that the first three of these can be rigorously expressed in arithmetical theories, albeit in theories which are either inconsistent or incomplete. The possibility of a well-structured example of the former alternative was not taken seriously, again because of belief in ECQ. However, in addition natural languages seem to have their own truth predicate. Combined with self-reference this produces the Liar paradox, "This sentence is false", an inconsistency. Priest (1987) and Priest, Routley, and Norman (1989) argued that the Liar had to be regarded as a statement both true and false, a true contradiction. This

represents another argument for studying inconsistent theories, namely the claim that some contradictions are true. Kripke (1975) proposed instead to model a truth predicate differently, in a consistent incomplete theory. We see below that incompleteness and inconsistency are closely related.

But mathematics is not its foundations. Hence there is a further independent motive, to see what mathematical structure remains when the constraint of consistency is relaxed. But it would be wrong to regard this as in any way a loss of structure. If it is different at all, then it represents an addition to known structure.

Robert K. Meyer (1976) seems to have been the first to think of an inconsistent arithmetical theory. At this point, he was more interested in the fate of a consistent theory, his relevant arithmetic R#. There proved to be a whole class of inconsistent arithmetical theories; see Meyer and Mortensen (1984), for example. Meyer argued that these theories provide the basis for a revived Hilbert Program. Hilbert's program was widely held to have been seriously damaged by Gödel's Second Incompleteness Theorem, according to which the consistency of arithmetic was unprovable within arithmetic itself. But a consequence of Meyer's construction was that within his arithmetic R# it was demonstrable by simple finitary means that whatever contradictions there might happen to be, they could not adversely affect any numerical calculations. Hence Hilbert's goal of conclusively demonstrating that mathematics is trouble-free proves largely achievable. The arithmetical models used later proved to allow inconsistent representation of the truth predicate. They also permit representation of structures beyond natural number arithmetic, such as rings and fields, including their order properties.

One could hardly ignore the examples of analysis and its special case, the calculus. There prove to be many places where there are distinctive inconsistent insights; see Mortensen (1995) for example. (1) Robinson's non-standard analysis was based on infinitesimals, quantities smaller than any real number, as well as their reciprocals, the infinite numbers. This has an inconsistent version, which has some advantages for calculation in being able to discard higher-order infinitesimals. Interestingly, the theory of differentiation turned out to have these advantages, while the theory of integration did not. (2) Another place is topology, where one readily observes the practice of cutting and pasting spaces being described as "identification" of one boundary with another. One can show that this can be described in an inconsistent theory in which the two boundaries are both identical and not identical, and it can be further argued that this is the most natural description of the practice. (3) Yet another application is the class of inconsistent continuous functions. Not all functions which are classically discontinuous are amenable of inconsistent treatment; but some are, for example $f(x)=0$ for all $x<0$ and $f(x)=1$ for all $x \geq 0$. The inconsistent extension replaces the first $<$ by $\leq$, and has distinctive structural properties. These inconsistent functions may well have some application in dynamic systems in which there are discontinuous jumps, such as quantum measurement systems. Differentiating such functions leads to the delta functions, applied by Dirac to the study of quantum measurement also. (4) Next, there is the well-known case of inconsistent systems of linear equations, such as the system (i) $x+y=1$, plus (ii) $x+y=2$. Such systems can potentially arise within the context of automated control. Little work has been done classically to solve such systems, but it can be shown that there are well-behaved solutions within inconsistent vector spaces. (5) Finally, one can note a further application in topology and dynamics. Given a supposition which seems to be conceivable, namely that whatever happens or is true, happens or

is true on an open set of (spacetime) points, one has that the logic of dynamically possible paths is open set logic, that is to say intuitionist logic, which supports incomplete theories par excellence. This is because the natural account of the negation of a proposition in such a space says that it holds on the largest open set contained in the Boolean complement of the set of points on which the original proposition held, which is in general smaller than the Boolean complement. However, specifying a topological space by its closed sets is every bit as reasonable as specifying it by its open sets. Yet the logic of closed sets is known to be paraconsistent, ie. supports inconsistent theories; see Goodman (1981) for example. Thus given the (alternative) supposition which also seems to be conceivable, namely that whatever is true is true on a closed set of points, one has that inconsistent theories may well hold. This is because the natural account of the negation of a proposition, namely that it holds on the smallest closed set containing the Boolean negation of the proposition, means that on the overlapping boundary both the proposition and its negation hold. Thus dynamical theories determine their own logic of possible propositions, and corresponding theories which may be inconsistent, and are certainly as natural as their incomplete counterparts.

Category theory throws light on many mathematical structures. It has certainly been proposed as an alternative foundation for mathematics. Such generality inevitably runs into problems similar to those of comprehension in set theory, see eg. Hatcher (1982, p.255-260). Hence there is the same possible application of inconsistent solutions. There is also an important collection of categorial structures, the toposes, which support open set logic in exact parallel to the way sets support Boolean logic. This has been taken by many to be a vindication of the foundational point of view of mathematical intuitionism. However, it can be proved that that toposes support closed set logic as readily as they support open set logic. That should not be viewed as an objection to intuitionism, however, so much as an argument that inconsistent theories are equally reasonable as items of mathematical study.

Duality between incompleteness/intuitionism and inconsistency/paraconsistency has at least two aspects. First there is the above topological (open/closed) duality. Second there is Routley * duality. Discovered by the Routleys (1972) as a semantical tool for relevant logics, the * operation dualises between inconsistent and incomplete theories of the large natural class of de Morgan logics. Both kinds of duality interact as well, where the * gives distinctive duality and invariance theorems for open set and closed set arithmetical theories. On the basis of these results, it is fair to argue that both kinds of mathematics, intuitionist and paraconsistent, are equally reasonable.

A very recent development is the application to explaining the phenomenon of inconsistent pictures. The best known of these are perhaps M.C.Escher's masterpieces *Belvedere, Waterfall* and *Ascending and Descending*. In fact the tradition goes back millennia to Pompeii. Escher seems to have derived many of his intuitions from the Swedish artist Oscar Reutersvaard, who began in 1934. Escher also actively collaborated with the English mathematician Roger Penrose. There have been several attempts to describe the mathematical structure of inconsistent pictures using classical consistent mathematics, by theorists such as Cowan, Francis and Penrose. As argued in Mortensen (1997), however, no consistent mathematical theory can capture the sense that one is seeing an impossible thing. Only an inconsistent theory can capture the content of that perception. This amounts to an appeal to cognition, that is the epistemological justification of paraconsistency as above. One can then proceed to describe inconsistent

theories which are candidates for such inconsistent contents. There is an analogy with classical mathematics on this point. Projective geometry is a mathematical theory which is interesting because we are creatures with an eye, since it explains why it is that things look the way they do in perspective.

These constructions do not in any way challenge or repudiate existing mathematics, but extend our conception of what is mathematically possible.

Dialetheism

A *dialetheia* is a true contradiction, a statement, *A*, such that both it and its negation, ¬*A*, are true. Hence, *dialeth(e)ism* is the view that there are true contradictions. Dialetheism opposes the so-called *Law of Non-Contradiction* (LNC) (sometimes also called the *Law of Contradiction*): for any *A*, it is impossible for both *A* and ¬*A* to be true. Since Aristotle's defence of the LNC, the Law has been orthodoxy in Western philosophy. Nonetheless, there are some dialetheists in the history of Western Philosophy. Moreover, since the development of paraconsistent logic in the second half of this century, dialetheism has now become a live issue once more. In the rest of this article, I will start by explaining the relationship between dialetheism and some other important concepts. Next, I will describe the history of dialetheism and the motivations for the modern dialetheic movement. I will then indicate and briefly discuss some of the objections to dialetheism, and its connections with the notion of rationality.

Some Basic Concepts

Though dialetheism is not a new view, the word itself is. It was coined by Graham Priest and Richard Routley (later Sylvan) in 1981 (see Priest, Routley and Norman, 1989, p. *xx*). The inspiration for the name was a passage in Wittgenstein's *Remarks on the Foundations of Mathematics*, where he describes the liar sentence (‘this sentence is not true’) as a Janus-headed figure facing both truth and falsity (1978, IV.59). Hence a di-aletheia is a two(-way) truth. Unfortunately, Priest and Routley forgot to agree how to spell the ‘ism’, and versions with and without the ‘e’ appear in print.

Dialetheism should be clearly distinguished from *trivialism*, the view that *all* contradictions are true (and hence, assuming that a conjunction entails its conjuncts, that everything is true). Though a trivialist must be a dialetheist, the converse is not the case. Dialetheism should also be clearly distinguished from *paraconsistency*. An inference relation, $\vdash$, is *explosive* if, according to it, a contradiction entails everything (for all A and B: $A, \neg A \vdash B$). It is paraconsistent iff it is not explosive. Dialetheists, unless they are also trivialists, must subscribe to the view that entailment (deductively valid inference) is paraconsistent. But one may subscribe to this view for other reasons; for example, that, though the actual truth is consistent, entailment must preserve what holds in non-actual situations, some of which may be inconsistent; or that entailment must preserve more than just truth, e.g., information content.

Dialetheism in the History of Philosophy

In Western Philosophy, a number of the Presocratics appear to have endorsed dialetheism. For example, in Fragment 49a, Heraclitus says: ‘We step and do not step into the same rivers; we are and we are not’ (Robinson, 1987, p. 35). At any rate, Aristotle appears to have taken Heraclitus, Protagoras and other Presocratics to be dialetheists, even trivialists. Their views triggered his attack in *Metaphysics*, Book Gamma. In Chapter 4 of this occurs Aristotle's defence of the LNC. Historically, this attack was almost completely successful: the LNC has been high orthodoxy in Western Philosophy ever since, as is witnessed by the fact that no one since Aristotle seems to have felt the need to provide a sustained defence of it. It is perhaps worth noting that in *Metaphysics* Gamma (Chapter 7) Aristotle also defends the dual of the LNC, the Law of Excluded Middle, LEM: for any A, it is necessary for (at least) one of A and $\neg A$ to be true. But the LEM has always had a less secure place in Western Philosophy than the LNC. Aristotle himself, in fact, attacks the Law in *De Interpretatione*, Ch.9.

Despite the orthodoxy about the LNC, there have been a few dialetheists since Aristotle. It is arguably the case that some of the Neoplatonists were dialetheists. Nicholas of Cusa, for example, held that God has all properties, including contradictory ones (Heron, 1954, I.4). And, according to some interpretations, Meinong was a dialetheist, holding that some non-existent objects, such as the round square, have inconsistent properties (see Routley, 1980, ch.5). But the most obvious dialetheists since the Presocratics and before the 20th century are Hegel and his successors in dialectics, such as Marx and Engels (see Priest 1990, 1991). According to these, reality (in the form of *Geist* for Hegel, or social structures for Marx) may be literally inconsistent. For example, in the *Logic*, Hegel says: ‘Something moves, not because at one moment it is here and another there, but because at one and the same moment it is here and not here, because in this "here", it at once is and is not’ (Miller, 1969, p. 440). Indeed, it is the resolution of these contradictory states that drives the development of the history of thought (or society) forwards.

Dialetheism appears to be a much more common and recurrent view in Eastern Philosophy than in the West. In ancient Indian logic/metaphysics, there were standardly four possibilities to be considered on any statement at issue: that it is true (only), false (only), neither true nor false, or *both*. Early Buddhist logic added a fifth possibility: none of these. (This was called the *catushkoti*.) The Jains went even

further and advocated the possibility of contradictory values of the kind: true (only) *and* both true and false. (Smart, 1964, has a discussion of the above issues.) Contradictory utterances are a commonplace in Taoism. For example, the *Chuang Tsu* says: ‘That which makes things has no boundaries with things, but for things to have boundaries is what we mean by saying "the boundaries between things". The boundaryless boundary is the boundary without a boundary’ (Mair, 1994, p. 218). When Buddhism and Taoism fused to form Chan (or Zen, to give it its Japanese name), a philosophy arose in which contradiction plays a central role. The very process for reaching enlightenment (*Prajna*) is a process, according to Suzuki (1969, p. 55), "which is at once above and in the process of reasoning. This is a contradiction, formally considered, but in truth, this contradiction is itself made possible because of Prajna."

Of course, interpreting the philosophers I have mentioned is a sensitive issue; and many commentators, especially Western ones who have wanted to make sense of their chosen philosopher whilst subscribing to the LNC, have suggested that the contradictory utterances of the philosopher in question are not really contradictory. There are a number of standard devices that may be employed here. One is to claim that the contradictory utterance is to be taken as having some non-literal form of meaning, e.g., that it is a metaphor. Another is to claim that the contradictory assertion is ambiguous in some way, and that it is true on one disambiguation (or in one respect) and false in another. It is certainly the case that contradictory utterances that one sometimes hears are best construed in some such way. Whether this is so in the case of the philosophers I have mentioned, is a matter for detailed case-by-case consideration. In most of these cases, it may be argued, such interpretations produce a manifestly inaccurate and distorted version of the views of the philosopher in question.

Modern Motivations for Dialetheism

Turning now to contemporary philosophy, the second half of the 20th century has seen a resurgence of dialetheism, driven by largely new considerations. This has been made possible by the modern construction and analysis of paraconsistent logics; in turn, it has been one of the motive forces behind this movement in logic.

Probably the major argument used by modern dialetheists invokes the paradoxes of self-reference, such as the liar paradox (‘this sentence is not true’), and Russell's paradox (concerning the set of all sets that are not members of themselves). Though paradoxes of this kind have been known since antiquity, they were thrown into prominence by developments in the foundations of mathematics at the turn of this century. In the case of each paradox, there appears to be a perfectly sound argument ending in a contradiction; and if the arguments are sound, then dialetheism is true. Of course, many have argued that the soundness of such arguments is merely an appearance, and that subtle fallacies may be diagnosed in them. Such suggestions were made in ancient and medieval logic; but many more have been made in modern logic--indeed, attacking the paradoxes has been something of a *leitmotiv* of modern logic. And one thing that appears to have come out of this is how resilient the paradoxes are: attempts to solve them often simply succeed in relocating the paradoxes elsewhere, as so called "strengthened" forms of the arguments show. There is, at any rate, no generally agreed upon solution to many of the paradoxes,

particularly those of a semantic (as opposed to set-theoretic) nature. It is these facts that give dialetheism about the paradoxes of self-reference one of its major appeals. It is not the only one, though: the simplicity of a dialetheic account of truth, to the effect that truth is simply characterised by the *T*-schema, is another.

The paradoxes of self reference are not the only examples of dialetheias that have been mooted. Others include the following. (1) Transition states: when I leave the room, for an instant I am both in it and not in it. (2) Some of Zeno's paradoxes: the moving arrow is both where it is, and where it is not. (3) Certain legal situations: there are laws to the effect that persons in category *A* must do something, and persons in category *B* may not do it. Someone in both categories then turns up. (4) Borderline cases of vague predicates: an adolescent is both an adult and not an adult. (5) Certain quantum mechanical states: a particle may go through two slits simultaneously, even though this is not possible. (6) Multi-criterial terms: where a term has more than one necessary and sufficient empirical criterion for application, and these fall apart in novel circumstances. The viability of all the preceding examples depends on detailed philosophical consideration, differing from case to case.

Objections to Dialetheism

I now turn to arguments against dialetheism. The only sustained defense of the LNC in the history of philosophy is, as I mentioned, that given by Aristotle in Chapter 4 of *Metaphysics*, Gamma. Given the influence this chapter has had, the arguments are surprisingly poor. Aristotle's main argument, which takes up the first half of chapter, is tangled and contorted. It is not clear what it is, let alone that it works. About the best one can say for it is that it depends on substantial and moot principles of Aristotelian metaphysics, and, in any case, as a suasive argument, begs the question. The six or seven arguments that Aristotle deploys in the second half of the chapter are varied, swift, and fare little better. Many of them seem also to beg the question. Worse: many of them simply confuse dialetheism and trivialism. (For an analysis of Aristotle's arguments, see Priest ,1998a.)

A standard modern argument against dialetheism is to invoke the logical principle of explosion, in virtue of which dialetheism would entail trivialism. Given that trivialism is absurd, which we may agree upon here (though why this is so is not as easy a question as it might appear), dialetheism must be rejected. It is clear that this argument will fail against someone who subscribes to a paraconsistent logic, as most dialetheists will.

Another argument that is sometimes deployed is as follows. A sentence is meaningful only if it rules something out. But if the LNC fails, *A* does not rule out $\neg A$ or, *a fortiori*, anything else. Hence meaningful language presupposes the LNC. There are many problems with this argument, but the central one is that the first premise is simply false. Consider the sentence ‘Everything is true’. This entails everything, and so rules out nothing. Yet it is quite meaningful. It is what everyone except a trivialist rejects.

Of the other arguments one might consider in this context, I will consider only one more, which goes as

follows. The truth conditions for negation are: $\neg A$ is true iff A is not true. Hence, if A and $\neg A$ were true, A would be both true and not true, which is impossible. The truth conditions for negation employed by this argument are contentious. (An alternative is that $\neg A$ is true iff A is *false*-- and in the semantics of many paraconsistent logics, truth and falsity may overlap.) But in any case, the argument fails, since it clearly begs the question at last step. Many other arguments for the LNC, whatever other they failings have, seem ultimately to beg the question in similar ways.

Dialetheism and Rationality

Some have felt that what is wrong with dialetheism is not so much violation of the LNC itself, as that an *acceptance* of the LNC is a precondition for rationality. For example, it is often suggested that it could not possibly be rational to accept a contradiction. Whilst the question of the conditions under which it is rational to accept something is a moot one, it is commonly agreed that, as Hume put it, the wise person 'proportions his beliefs to the evidence' (1955, p. 118). Hence, if a sufficient case can be made out for a contradiction, it will be rational to believe it. And cases there are. For example, the case for the truth of the liar sentence, 'this sentence is not true', was gestured at in the previous section. And whether or not one takes the case in question to be completely persuasive, it illustrates the fact that there is nothing in principle impossible about the existence of such a case. Of course, if there were *conclusive* evidence for the LNC, then no case for a contradiction could be strong enough. But conclusive evidence for any philosophical position is virtually impossible.

A more persuasive worry about dialetheism, relating to rationality, is the claim that if a person could legitimately accept a contradiction, then no one could be forced, rationally, to abandon a view held. For if a person accepts A then, when an argument for $\neg A$ is put up, they could simply accept both A and $\neg A$. But this is too fast. The fact that some contradictions are rationally acceptable does not entail that all are. There is certainly a case that the liar sentence is both true and false, but this in no way provides a case that Brisbane is and is not in Australia. (Of course, if one subscribes to the claim that entailment is explosive, a case for one contradiction is a case for all; but if entailment is paraconsistent, this argument is of no use.) As orthodox philosophy of science indicates, there are, in fact, many considerations that speak against the rational acceptability of a view: that it is unduly complex, that it is contrived, that it has observable consequences that are not observed. (*Why* these are negative criteria is a different--and often difficult--question.) And these criteria may speak against the acceptability of a view, whether it is consistent or inconsistent. In the end, the rational evaluation of a view must balance it against all criteria of this kind (of which, inconsistency is, arguably, one), each, on its own, being defeasible.

Conclusion

I think it fair to say that since Aristotle's defence of the LNC, consistency has been something of a shibboleth in Western philosophy. The thought that consistency is a *sine qua non* for central notions such as validity, truth, meaningfulness, rationality, is deeply ingrained into its psyche. One thing that has come out of the modern investigations into dialetheism appears to be how superficial such a thought is. If

consistency is, indeed, a necessary condition for any of these notions it would seem to be for reasons much deeper than anyone has yet succeeded in articulating. And if it is not, then the way is open for the exploration of all kinds of avenues and questions in philosophy and the sciences that have traditionally been closed off.

Aristotle's Metaphysics

The first major work in the history of philosophy to bear the title “Metaphysics” was the treatise by Aristotle that we have come to know by that name. But Aristotle himself did not use that title or even describe his field of study as ‘metaphysics’; the name was evidently coined by the first century C.E. editor who assembled the treatise we know as Aristotle's *Metaphysics* out of various smaller selections of Aristotle's works. The title ‘metaphysics’ — literally, ‘after the *Physics*’ — very likely indicated the place the topics discussed therein were intended to occupy in the philosophical curriculum. They were to be studied after the treatises dealing with nature (*ta phusika*). In this entry, we discuss the ideas that are developed in Aristotle's treatise.

§1. The Subject Matter of Aristotle's Metaphysics

Aristotle himself described his subject matter in a variety of ways: as ‘first philosophy’, or ‘the study of being qua being’, or ‘wisdom’, or ‘theology’. A comment on these descriptions will help to clarify Aristotle's topic.

In *Metaphysics* A.1, Aristotle says that “all men suppose what is called wisdom (*sophia*) to deal with the first causes (*aitia*) and the principles (*archai*) of things” (981b28), and it is these causes and principles that he proposes to study in this work. It is his customary practice to begin an inquiry by reviewing the opinions previously held by others, and that is what he does here, as Book A continues with a history of the thought of his predecessors about causes and principles.

These causes and principles are clearly the subject matter of what he calls ‘first philosophy’. But this does not mean the branch of philosophy that should be studied first. Rather, it concerns issues that are in some sense the most fundamental or at the highest level of generality. Aristotle distinguished between things that are “better known to us” and things that are “better known in themselves,”[1] and maintained that we should begin our study of a given topic with things better known to us and arrive ultimately at an understanding of things better known in themselves. The principles studied by ‘first philosophy’ may seem very general and abstract, but they are, according to Aristotle, better known in themselves, however remote they may seem from the world of ordinary experience. Still, since they are to be studied only by one who has already studied nature (which is the subject matter of the *Physics*), they are quite appropriately described as coming “after the *Physics*.”

Aristotle's description ‘the study of being qua being’ is frequently and easily misunderstood, for it seems to suggest that there is a single (albeit special) subject matter — being qua being — that is under investigation. But Aristotle's description does not involve two things — (1) a study and (2) a subject matter (being qua being) — for he did not think that there is any such subject matter as ‘being qua being’. Rather, his description involves three things: (1) a study, (2) a subject matter (being), and (3) a manner in which the subject matter is studied (qua being).

Aristotle's Greek word that has been Latinized as ‘qua’ means roughly ‘in so far as’ or ‘under the aspect’. A study of *x* qua *y*, then, is a study of *x* that concerns itself solely with the *y* aspect of *x*. So Aristotle's study does not concern some recondite subject matter known as ‘being qua being’. Rather it is a study of being, or better, of beings — of things that can be said to be — that studies them in a particular way: as beings, in so far as they are beings.

Of course, first philosophy is not the only field of inquiry to study beings. Natural science and mathematics also study beings, but in different ways, under different aspects. The natural scientist studies them as things that are subject to the laws of nature, as things that move and undergo change. That is, the natural scientist studies things qua movable (i.e., in so far as they are subject to change). The mathematician studies things qua countable and measurable. The metaphysician, on the other hand,

studies them in a more general and abstract way — qua beings. So first philosophy studies the causes and principles of beings qua beings. In Γ.2, Aristotle adds that for this this reason it studies the causes and principles of substances (*ousiai*). We will explain this connection in §3 below.

In Book E, Aristotle adds another description to the study of the causes and principles of beings qua beings. Whereas natural science studies objects that are material and subject to change, and mathematics studies objects that although not subject to change are nevertheless not separate from (i.e., independent of) matter, there is still room for a science that studies things (if indeed there are any) that are eternal, not subject to change, and independent of matter. Such a science, he says, is theology, and this is the "first" and "highest" science. Aristotle's identification of theology, so conceived, with the study of being qua being has proved challenging to his interpreters. We will deal with this issue in §14 below.

Finally, we may note that in Book B, Aristotle delineates his subject matter in a different way, by listing the problems or perplexities (*aporiai*) he hopes to deal with. Characteristic of these perplexities, he says, is that they tie our thinking up in knots. They include the following, among others: Are sensible substances the only ones that exist, or are there others besides them? Is it kinds or individuals that are the elements and principles of things? And if it is kinds, which ones: the most generic or the most specific? Is there a cause apart from matter? Is there anything apart from material compounds? Are the principles limited, either in number or in kind? Are the principles of perishable things themselves perishable? Are the principles universal or particular, and do they exist potentially or actually? Are mathematical objects (numbers, lines, figures, points) substances? If they are, are they separate from or do they always belong to sensible things? And ("the hardest and most perplexing of all," Aristotle says) are unity and being the substance of things, or are they attributes of some other subject? In the remainder of Book B, Aristotle presents arguments on both sides of each of these issues, and in subsequent books he takes up many of them again. But it is not always clear precisely how he resolves them, and it is possible that Aristotle did not think that the *Metaphysics* contains definitive solutions to all of these perplexities.

§2. The Categories

To understand the problems and project of Aristotle's *Metaphysics*, it is best to begin with one of his earlier works, the *Categories*. Although placed by long tradition among his logical works (see the discussion in the entry on Aristotle's logic), due to its analysis of the terms that make up the propositions out of which deductive inferences are constructed, the *Categories* begins with a strikingly general and exhaustive account of the things there are (*ta onta*) — beings. According to this account, beings can be divided into ten distinct categories. (Although Aristotle never says so, it is tempting to suppose that these categories are mutually exclusive and jointly exhaustive of the things there are.) They include substance, quality, quantity, and relation, among others. Of these categories of beings, it is the first, substance (*ousia*), to which Aristotle gives a privileged position.

Substances are unique in being independent things; the items in the other categories all depend somehow on substances. That is, qualities are the qualities of substances; quantities are the amounts and sizes that substances come in; relations are the way substances stand to one another. These various non-substances

all owe their existence to substances — each of them, as Aristotle puts it, exists only 'in' a subject. That is, each non-substance "is in something, not as a part, and cannot exist separately from what it is in" (*Cat*. 1a25). Indeed, it becomes clear that substances are the subjects that these ontologically dependent non-substances are 'in'.

Each member of a non-substance category thus stands in this inherence relation (as it is frequently called) to some substance or other — color is always found in bodies, knowledge in the soul. Neither whiteness nor a piece of grammatical knowledge, for example, is capable of existing on its own. Each requires for its existence that there be some substance in which it inheres.

In addition to this fundamental inherence relation across categories, Aristotle also points out another fundamental relation that obtains between items within a single category. He describes this as the relation of "being said of a subject," and his examples make clear that it is the relation of a more general to a less general thing within a single category. Thus, man is 'said of' a particular man, and animal is 'said of' man, and therefore, as Aristotle points out, animal is 'said of' the particular man also. The 'said of' relation, that is to say, is transitive (cf. 1b10). So the genus (e.g., animal) is 'said of' the species (e.g., man) and both genus and species are 'said of' the particular. The same holds in non-substance categories. In the category of quality, for example, the genus (color) is 'said of' the species (white) and both genus and species are 'said of' the particular white. (There has been considerable scholarly dispute about these particulars in nonsubstance categories. For more detail, see the supplementary document Nonsubstantial Particulars.)

The language of this contrast ('in' a subject vs. 'said of' a subject) is peculiar to the *Categories*, but the idea seems to recur in other works as the distinction between accidental vs. essential predication. Similarly, in works other than the *Categories,* Aristotle uses the label 'universals' (*ta katholou*) for the things that are "said of many;" things that are not universal he calls 'particulars' (*ta kath' hekasta*). Although he does not use these labels in the *Categories*, it is not misleading to say that the doctrine of the *Categories* is that each category contains a hierarchy of universals and particulars, with each universal being 'said of' the lower-level universals and particulars that fall beneath it. Each category thus has the structure of an upside-down tree.[2] At the top (or trunk) of the tree are the most generic items in that category[3] (e.g., in the case of the category of substance, the genus plant and the genus animal); branching below them are universals at the next highest level, and branching below these are found lower levels of universals, and so on, down to the lowest level universals (e.g., such *infimae species* as man and horse); at the lowest level — the leaves of the tree — are found the individual substances, e.g., this man, that horse, etc.

The individuals in the category of substance play a special role in this scheme. Aristotle calls them "primary substances" (*prôtai ousiai*) for without them, as he says, nothing else would exist. Indeed, Aristotle offers an argument (2a35-2b7) to establish the primary substances as the fundamental entities in this ontology. Everything that is not a primary substance, he points out, stands in one of the two relations (inhering 'in', or being 'said of') to primary substances. A genus, such as animal, is 'said of' the species below it and, since they are 'said of' primary substances, so is the genus (recall the transitivity of the 'said

of' relation). Thus, everything in the category of substance that is not itself a primary substance is, ultimately, 'said of' primary substances. And if there were no primary substances, there would be no "secondary" substances (species and genera), either. For these secondary substances are just the ways in which the primary substances are fundamentally classified within the category of substance. As for the members of non-substance categories, they too depend for their existence on primary substances. A universal in a non-substance category, e.g., color, in the category of quality, is 'in' body, Aristotle tells us, and therefore in individual bodies. For color could not be 'in' body, in general, unless it were 'in' at least some particular bodies. Similarly, particulars in non-substance categories (although there is not general agreement among scholars about what such particulars might be) cannot exist on their own. E.g., a determinate shade of color, or a particular and non-shareable bit of that shade, is not capable of existing on its own — if it were not 'in' at least some primary substance, it would not exist. So primary substances are the basic entities — the basic "things that there are" — in the world of the *Categories*.

§3. The Role of Substance in the Study of Being Qua Being

The *Categories* leads us to expect that the study of being in general (being qua being) will crucially involve the study of substance, and when we turn to the *Metaphysics* we are not disappointed. First, in *Metaphysics* Γ Aristotle argues in a new way for the ontological priority of substance; and then, in Books Z, H, and Θ, he wrestles with the problem of what it is to be a substance. We will begin with Γ's account of the central place of substance in the study of being qua being.

As we noted above, metaphysics (or, first philosophy) is the science which studies being qua being. In this respect it is unlike the specialized or departmental sciences, which study only part of being (only some of the things that exist) or study beings only in a specialized way (e.g., only in so far as they are changeable, rather than in so far as they are beings).

But 'being', as Aristotle tells us in Γ.2, is "said in many ways". That is, the verb 'to be' (*einai*) has different senses, as do its cognates 'being' (*on*) and 'entities' (*onta*). So the universal science of being qua being appears to founder on an equivocation: how can there be a single science of being when the very term 'being' is ambiguous?

Consider an analogy. There are dining tables, and there are tide tables. A dining table is a table in the sense of a smooth flat slab fixed on legs; a tide table is a table in the sense of a systematic arrangement of data in rows and columns. But there is not a single sense of 'table' which applies to both the piece of furniture at which I am writing these words and to the small booklet that lies upon it. Hence it would be foolish to expect that there is a single science of tables, in general, that would include among its objects both dining tables and tide tables. Tables, that is to say, do not constitute a single kind with a single definition, so no single science, or field of knowledge, can encompass precisely those things that are correctly called 'tables'.

If the term ‘being’ were ambiguous in the way that ‘table’ is, Aristotle's science of being qua being would be as impossible as a science of tables qua tables. But, Aristotle argues in Γ.2, ‘being’ is not ambiguous in this way. ‘Being’, he tells us, is ‘said in many ways’ but it is not merely (what he calls) ‘homonymous’, i.e., sheerly ambiguous. Rather, the various senses of ‘being’ have what he calls a ‘*pros hen*’ ambiguity — they are all related to a single central sense. (The Greek phrase ‘*pros hen*’ means “in relation to one.”)

Aristotle explains his point by means of some examples that he takes to be analogous to ‘being’. Consider the terms ‘healthy’ and ‘medical’. Neither of these has a single definition that applies uniformly to all cases: not every healthy (or medical) thing is healthy (medical) in the same sense of ‘healthy’ (‘medical’). There is a range of things that can be called ‘healthy’: people, diets, exercise, complexions, etc. Not all of these are healthy in the same sense. Exercise is healthy in the sense of being productive of health; a clear complexion is healthy in the sense of being symptomatic of health; a person is healthy in the sense of having good health.

But notice that these various senses have something in common: a reference to one central thing, health, which is actually possessed by only some of the things that are spoken of as ‘healthy’, namely, healthy organisms, and these are said to be healthy in the primary sense of the term. Other things are considered healthy only in so far as they are appropriately related to things that are healthy in this primary sense.

The situation is the same, Aristotle claims, with the term ‘being’. It, too, has a primary sense as well as related senses in which it applies to other things because they are appropriately related to things that are called ‘beings’ in the primary sense. The beings in the primary sense are substances; the beings in other senses are the qualities, quantities, etc., that belong to substances. An animal, e.g., a horse, is a being, and so is a color, e.g, white, a being. But a horse is a being in the primary sense — it is a substance — whereas the color white (a quality) is a being only because it qualifies some substance. An account of the being of anything that is, therefore, will ultimately have to make some reference to substance. Hence, the science of being qua being will involve an account of the central case of beings — substances.

§4. The Fundamental Principles: Axioms

Before embarking on this study of substance, however, Aristotle goes on in Book Γ to argue that first philosophy, the most general of the sciences, must also address the most fundamental principles — the common axioms — that are used in all reasoning. Thus, first philosophy must also concern itself with the principle of non-contradiction (PNC): the principle that “the same attribute cannot at the same time belong and not belong to the same subject and in the same respect” (1005b19). This, Aristotle says, is the most certain of all principles, and it is not just a hypothesis. It cannot, however, be proved, since it is employed, implicitly, in all proofs, no matter what the subject matter. It is a first principle, and hence is not derived from anything more basic.

What, then, can the science of first philosophy say about the PNC? It cannot offer a proof of the PNC, since the PNC is presupposed by any proof one might offer — any purported proof of the PNC would therefore be circular. Aristotle thus does not attempt to prove the PNC; in the subsequent chapters of Γ he

argues, instead, that it is impossible to disbelieve the PNC. Those who would claim to deny the PNC cannot, if they have any beliefs at all, believe that it is false. For one who has a belief must, if he is to express this belief to himself or to others, say something — he must make an assertion. He must, as Aristotle says, signify something. But the very act of signifying something is possible only if the PNC is accepted. Without accepting the PNC, one would have no reason to think that his words have any signification at all — they could not mean one thing rather than another. So anyone who makes any assertion has already committed himself to the PNC. Aristotle thus does not argue that the PNC is a necessary truth (that is, he does not try to prove the PNC); rather, he argues that the PNC is indubitable. (For more on the PNC, see the discussion in the entry on Aristotle's logic)

§5. What is Substance?

In the seventeen chapters that make up Book Z of the *Metaphysics*, Aristotle takes up the promised study of substance. He begins by reiterating and refining some of what he said in Γ: that 'being' is said in many ways, and that the primary sense of 'being' is the sense in which substance are beings. Here, however, he explicitly links the secondary senses of 'being' to the non-substance categories. The primacy of substance leads Aristotle to say that the age-old question 'What is being?' "is just the question 'What is substance?'" (1028b4).

One might have thought that this question had already been answered in the *Categories*. There we were given, as examples of primary substances, an individual man or horse, and we learned that a primary substance is "what is neither in a subject nor said of a subject" (2a10). This would seem to provide us with both examples of, and criteria for being, primary substances. But in *Metaphysics* Z, Aristotle does not seem to take either the examples or the criteria for granted.

In Z.2 he recounts the various answers that have been given to the question of which things are substances — bodies (including plants, animals, the parts of plants and animals, the elements, the heavenly bodies), things more basic than bodies (surfaces, lines, and points), imperceptible things (such as Platonic Forms and mathematical objects) — and seems to regard them all as viable candidates at this point. He does not seem to doubt that the clearest examples of substances are perceptible ones, but leaves open the question whether there are others as well.

Before answering this question about examples, however, he says that we must first answer the question about criteria: what is it to be a substance (*tên ousian prôton ti estin*)? The negative criterion ("neither in a subject nor said of a subject") of the *Categories* tells us only which things are substances. But even if we know *that* something is a substance, we must still say what *makes* it a substance — what the cause is of its being a substance. This is the question to which Aristotle next turns. To answer it is to identify, as Aristotle puts it, the substance *of* that thing.

§6. Substance, Matter, and Subject

Z.3 begins with a list of four possible candidates for being the substance of something: essence, universal, genus, and subject. Presumably, this means that if *x* is a substance, then the substance of *x* might be either (i) the essence of *x*, or (ii) some universal predicated of *x*, or (iii) a genus that *x* belongs to, or (iv) a subject of which *x* is predicated. The first three candidates are taken up in later chapters, and Z.3 is devoted to an examination of the fourth candidate: the idea that the substance of something is a subject of which it is predicated.

A subject, Aristotle tells us, is “that of which everything else is predicated, while it is itself not predicated of anything else” (1028b36). This characterization of a subject is reminiscent of the language of the *Categories*, which tells us that a primary substance is not predicated of anything else, whereas other things are predicated of it. Candidate (iv) thus seems to reiterate the *Categories* criterion for being a substance. But there are two reasons to be wary of drawing this conclusion. First, whereas the subject criterion of the *Categories* told us that substances were the ultimate subjects of predication, the subject criterion envisaged here is supposed to tell us what the substance *of* something is. So what it would tell us is that if *x* is a substance, then the substance of *x* — that which makes *x* a substance — is a subject that *x* is predicated of. Second, as his next comment makes clear, Aristotle has in mind something other than this *Categories* idea. For the subject that he here envisages, he says, is either matter or form or the compound of matter and form. These are concepts from Aristotle's *Physics*, and none of them figured in the ontology of the *Categories*. To appreciate the issues Aristotle is raising here, we must briefly compare his treatment of the notion of a subject in the *Physics* with that in the *Categories*.

In the *Categories*, Aristotle was concerned with subjects of predication: what are the things we talk about, and ascribe properties to? In the *Physics*, his concern is with subjects of change: what is it that bears (at different times) contrary predicates and persists through a process of change? But there is an obvious connection between these conceptions of a subject, since a subject of change must have one predicate belonging to it at one time that does not belong to it at another time. Subjects of change, that is, are also subjects of predication. (The converse is not true: numbers are subjects of predication — six is even, seven is prime — but not of change.)

In the *Categories*, individual substances (a man, a horse) were treated as fundamental subjects of predication. They were also understood, indirectly, as subjects of change. (“A substance, one and the same in number, can receive contraries. An individual man, for example, being one and the same, becomes now pale and now dark, now hot and now cold, now bad and now good” 4a17-20.) These are changes in which substances move, or alter, or grow. What the *Categories* did not explore, however, are changes in which substances are generated or destroyed. But the theory of change Aristotle develops in the *Physics* requires some other subject for changes such as these — a subject of which substance is predicated — and it identifies matter as the fundamental subject of change (192a31-32). Change is seen in the *Physics* as a process in which matter either takes on or loses form.

The concepts of matter and form, as we noted, are absent from the *Categories*. Individual substances — this man or that horse — apart from their accidental characteristics — the qualities, etc., that inhere in them — are viewed in that work as essentially simple, unanalyzable atoms. Although there is metaphysical structure to the fact that, e.g., *this horse is white* (a certain quality inheres in a certain

substance), the fact that *this is a horse* is a kind of brute fact, devoid of metaphysical structure. This horse is a primary substance, and *horse,* the species to which it belongs, is a secondary substance. But there is no predicative complex corresponding to the fact that this is a horse in the way that there is such a complex corresponding to the fact that this horse is white.

But from the point of view of the *Physics,* substantial individuals are seen as predicative complexes (cf. Matthen 1987); they are hylomorphic compounds — compounds of matter and form — and the subject criterion looks rather different from the hylomorphic perspective. *Metaphysics* Z.3 examines the subject criterion from this perspective.

Matter, form, and the compound of matter and form may all be considered subjects, Aristotle tells us, (1029a2-4), but which of them is substance? The subject criterion by itself leads to the answer that the substance of *x* is an entirely indeterminate matter of which *x* is composed (1029a10). For form is predicated of matter as subject, and one can always analyze a hylomorphic compound into its predicates and the subject of which they are predicated. And when all predicates have been removed (in thought), the subject that remains is nothing at all in its own right — an entity all of whose properties are accidental to it (1029a12-27). The resulting subject is matter from which all form has been expunged. (Traditional scholarship calls this "prime matter," but Aristotle does not here indicate whether he thinks there actually is such a thing.) So the subject criterion leads to the answer that the substance of *x* is the formless matter of which it is ultimately composed.

But Aristotle rejects this answer as impossible (1029a28), claiming that substance must be "separate" (*chôriston*) and "some this" (*tode ti*, sometimes translated "this something"), and implying that matter fails to meet this requirement. Precisely what the requirement amounts to is a matter of considerable scholarly debate, however. A plausible interpretation runs as follows. Being separate has to do with being able to exist independently (*x* is separate from *y* if *x* is capable of existing independently of *y*), and being some this means being a determinate individual. So a substance must be a determinate individual that is capable of existing on its own. (One might even hold, although this is controversial, that on Aristotle's account not every "this" is also "separate." A particular color or shape might be considered a determinate individual that is not capable of existing on its own — it is always the color of shape of some substance or other.) But matter fails to be simultaneously both *chôriston* and *tode ti*. The matter of which a substance is composed may exist independently of that substance (think of the wood of which a desk is composed, which existed before the desk was made and may survive the disassembly of the desk), but it is not as such any definite individual — it is just a quantity of a certain kind of matter. Of course, the matter may be construed as constituting a definite individual substance (the wood just *is*, one might say, the particular desk it composes), but it is in that sense not separate from the form or shape that makes it that substance (the wood cannot be that particular desk unless it is *a* desk). So although matter is in a sense separate and in a sense some this, it cannot be both separate and some this. It thus does not qualify as the substance of the thing whose matter it is.

§7. Substance and Essence

Aristotle turns in Z.4 to a consideration of the next candidate for substance: essence. (‘Essence’ is the standard English translation of Aristotle's curious phrase *to ti ên einai*, literally “the what it was to be” for a thing. This phrase so boggled his Roman translators that they coined the word *essentia* to render the entire phrase, and it is from this Latin word that ours derives. Aristotle also sometimes uses the shorter phrase *to ti esti*, literally “the what it is,” for approximately the same idea.) In his logical works, Aristotle links the notion of essence to that of definition (*horismos*) — “a definition is an account (*logos*) that signifies an essence” (*Topics* 102a3) — and he links both of these notions to a certain kind of *per se* predication (*kath' hauto*, literally, “in respect of itself”) — “what belongs to a thing in respect of itself belongs to it in its essence (*en tôi ti esti*)” for we refer to it “in the account that states the essence” (*Posterior Analytics*, 73a34-5). He reiterates these ideas in Z.4: “there is an essence of just those things whose *logos* is a definition” (1030a6), “the essence of a thing is what it is said to be in respect of itself” (1029b14). It is important to remember that for Aristotle, one defines things, not words. The definition of tiger does not tell us the meaning of the word ‘tiger’; it tells us what it is to be a tiger, what a tiger is said to be in respect of itself. Thus, the definition of tiger states the essence — the “what it is to be” of a tiger, what is predicated of the tiger *per se*.

Aristotle's preliminary answer (Z.4) to the question “What is substance?” is that substance is essence, but there are important qualifications. For, as he points out, “definition (*horismos*), like ‘what it is’ (*ti esti*), is said in many ways” (1030a19). That is, items in all the categories are definable, so items in all the categories have essences — just as there is an essence of man, there is also an essence of white and an essence of musical. But, because of the *pros hen* equivocity of ‘is’, such essences are secondary — “definition and essence are primarily (*protôs*) and without qualification (*haplôs*) of substances” (1030b4-6). Thus, Z.4 tells us, it is only these primary essences that are substances. Aristotle does not here work out the details of this “hierarchy of essences” (Loux, 1991), but it is possible to reconstruct a theory of such a hierarchy on the basis of subsequent developments in Book Z.

In Z.6, Aristotle goes on to argue that if something is “primary” and “spoken of in respect of itself (*kath' hauto legomenon*)” it is one and the same as its essence. The precise meaning of this claim, as well as the nature and validity of the arguments offered in support of it, are matters of scholarly controversy. But it does seem safe to say that Aristotle thinks that an “accidental unity” such as a pale man is not a *kath' hauto legomenon* (since pallor is an accidental characteristic of a man) and so is not the same as its essence. *Pale man*, that is to say, does not specify the “what it is” of any primary being, and so cannot be an essence of the primary kind. As Z.4 has already told us, “only species of a genus have an essence” (1030a11-12) in the primary sense. *Man* is a species, and so there is an essence of man; but *pale man* is not a species and so, even if there is such a thing as the essence of pale man, it is not, at any rate, a primary essence.

At this point there appears to be a close connection between the essence of a substance and its species (*eidos*), and this might tempt one to suppose that Aristotle is identifying the substance of a thing (since the substance of a thing is its essence) with its species. (A consequence of this idea would be that Aristotle is radically altering his conception of the importance of the species, which in the *Categories* he called a secondary substance, that is, a substance only in a secondary sense.) But such an identification would be a mistake, for two reasons. First, Aristotle's point at 1030a11 is not that a species is an essence,

but that an essence of the primary kind corresponds to a species (e.g., *man*) and not to some more narrowly delineated kind (e.g., *pale man*). Second, the word ‘*eidos*’, which meant ‘species’ in the logical works, has acquired a new meaning in a hylomorphic context, where it means ‘form’ (contrasted with ‘matter’) rather than ‘species’ (contrasted with ‘genus’). In the conceptual framework of *Metaphysics* Z, a universal such as *man* or *horse* — which was called a species and a secondary substance in the *Categories* — is construed as “not a substance, but a compound of a certain formula and a certain matter, taken universally” (Z.10, 1035b29-30). The *eidos* that is primary substance in Book Z is not the species that an individual substance belongs to but the form that is predicated of the matter of which it is composed (Cf. Driscoll 1981).

§8. Substances as Hylomorphic Compounds

The role of form in this hylomorphic context is the topic of Z.7-9. (Although these chapters were almost certainly not originally included in Book Z — there is no reference to them, for example, in the summary of Z given in H.1, which skips directly from Z.6 to Z.10 — they provide a link between substance and form and thus fill what would otherwise be a gap in the argument.) Since individual substances are seen as hylomorphic compounds, the role of matter and form in their generation must be accounted for. Whether we are thinking of natural objects, such as plants and animals, or artifacts, such as houses, the requirements for generation are the same. We do not produce the matter (to suppose that we do leads to an infinite regress) nor do we produce the form (what could we make it out of?); rather, we put the form into the matter, and produce the compound (Z.8, 1033a30-b9). Both the matter and the form must pre-exist (Z.9, 1034b12). But the source of motion in both cases — what Aristotle calls the “moving cause” of the coming to be — is the form.

In artistic production, the form is found in the soul of the artisan, for “the art of building is the form of the house” (1034a24) and “the form is in the soul” (1032b23) of the artisan. For example, the builder has in mind the plan or design for a house and he knows how to build; he then “enmatters” that plan or design by putting it into the materials out of which he builds the house. In natural production, the form is found in the parent, where “the begetter is the same in kind as the begotten, not one in number but one in form — for man begets man” (1033b30-2). But in either case, the form pre-exists and is not produced (1033b18).

As for what is produced in such hylomorphic productions, it is correctly described by the name of its form, not by that of its matter. What is produced is a house or a man, not bricks or flesh. Of course, what is made of gold may still be described in terms of its material components, but we should call it not “gold” but “golden” (1033a7). For if gold is the matter out of which a statue is made, there was gold present at the start, and so it was not gold that came into being. It was a statue that came into being, and although the statue is golden — i.e., made of gold — it cannot be identified with the gold of which it was made.

The essence of such a hylomorphic compound is evidently its form, not its matter. As Aristotle says “by form I mean the essence of each thing, and its primary substance” (1032b1), and “when I speak of

substance without matter I mean the essence” (1032b14). It is the form of a substance that makes it the kind of thing that it is, and hence it is form that satisfies the condition initially required for being the *substance of* something. The substance of a thing is its form.

§9. Substance and Definition

In Z.10 and 11, Aristotle returns to the consideration of essence and definition left off in Z.6, but now within the hylomorphic context developed in Z.7-9. The main question these chapters consider is whether the definition of *x* ever includes a reference to the matter of *x*. If some definitions include a reference to matter, then the link between essence and form would seem to be weakened.

Aristotle begins Z.10 by endorsing the following principle about definitions and their parts: “a definition is an account, and every account has parts, and part of the account stands to part of the thing in just the same way that the whole account stands to the whole thing” (1034b20-22). That is, if *y* is a part of a definable thing *x*, then the definition of *x* will include as a part something *z* that corresponds to *y*. Indeed, *z* must stand to *y* in the same relation that the definition of *x* stands in to *x*; that is, *z* is the definition of *y*. So, according to this principle, the definition of a thing will include the definitions of its parts.

In a way, this consequence of the principle seems very plausible, given Aristotle's idea that it is universals that are definable (Z.11, 1036a29). Consider as a definiendum a universal, such as *man*, and its definiens, *rational animal*. The parts of this definiens are the universals *rational* and *animal*. If these parts are, in turn, definable, then each should be replaced, in the definition of *man*, with its own definition, and so on. In this way the complete and adequate definition of a universal such as *man* will contain no parts that are further definable. All proper, or completely analyzed, definitions are ultimately composed of simple terms that are not further definable.

But the implication of this idea for the definitions of hylomorphic compounds is obvious: since matter appears to be a part of such a compound, the definition of the compound will include, as a part, the definitions of its material components. And this consequence seems implausible to Aristotle. A circle, for example, seems to be composed of two semicircle (for it obviously may be divided into two semicircle), but the definition of *circle* cannot be composed of the definitions of its two semicircular parts. For, as Aristotle points out (1035b9), *semicircle* is defined in terms of *circle*, and not the other way around. His point is well taken, for if circles were defined in terms of semicircles, then presumably semicircles would be defined in terms of the quarter-circles of which they are composed, and so on, *ad infinitum*. The resulting infinite regress would make it impossible to define *circle* at all, for one would never reach the ultimate “simple” parts of which such a definition would be composed.

Aristotle flirts with the idea of distinguishing between different senses in which one thing can be a part of another (1034b33), but instead proposes a different solution: to specify carefully the whole of which the matter is allegedly a part. “The bronze is part of the compound statue, but not of the statue spoken of as form” (1035a6). Similarly, “the line when divided passes away into its halves, and the man into bones and muscle and flesh, but it does not follow that they are composed of these as parts of their essence”

(1035a17-20). Rather, “it is not the substance but the compound that is divided into the body and its parts as into matter” (1035b21-2).

In restating his point “yet more clearly” (1035b4), Aristotle notes parenthetically another important aspect of his theory of substance. He reiterates the priority of form, and its parts, to the matter into which a compound is divided, and notes that “the soul of animals (for this is the substance of living things) is their substance” (1035b15). The idea recurs in Z.11, where he announces that “it is clear that the soul is the primary substance and the body is matter” (1037a5). It is further developed, in the *Metaphysics*, in Z.17, as we will see below, and especially in *De Anima*. For more detail on this topic, see the entry on Aristotle's psychology.

Returning now to the problem raised by the apparent need to refer to matter in the definition of a substance, we may note that the solution Aristotle offered in Z.10 is only partially successful. His point seems to be that whereas bronze may be a part of a particular statue, neither that particular batch of bronze nor even bronze in general enters into the essence of statue, since being made of bronze is no part of what it is to be a statue. But that is only because statues, although they must be made of some kind of matter, do not require any particular kind of matter. But what about kinds of substances that do require particular kinds of matter? Aristotle's distinction between form and compound cannot be used in such cases to isolate essence from matter. Thus there may after all be reasons for thinking that reference to matter will have to intrude into at least some definitions.

In Z.11, Aristotle addresses just such a case (although the passage is difficult and there is disagreement over its interpretation). “The form of man is always found in flesh and bones and parts of this kind,” Aristotle writes (1036b4). The point is not just that each particular man must be made of matter, but that each one must be made of matter of a particular kind — flesh and bones, etc. “Some things,” he continues, “surely are a particular form in a particular matter” (1036b23), so that it is not possible to define them without reference to their material parts (1036b28). Nevertheless, Aristotle ends Z.11 as if he has defended the claim that definition is of the form alone. Perhaps his point is that whenever it is essential to a substance that it be made of a certain kind of matter (e.g., that man be made of flesh and bones, or that “a saw cannot be made of wool or wood,” H.4, 1044a28) this is in some sense a formal or structural requirement. A kind of matter, after all, can itself be analyzed hylomorphically — bronze, for example, is a mixture of copper and tin according to a certain ratio or formula (*logos*), which is in turn predicated of some more generic underlying subject. The reference to matter in a definition will thus always be to a certain kind of matter, and hence to a predicate, rather than a subject. At any rate, if by ‘matter’ one has in mind the ultimate subject alluded to in Z.3 (so-called ‘prime matter’), there will be no reference to it in any definition, “for this is indefinite” (1037a27).

Z.12 introduces a new problem about definitions — the so-called “unity of definition.” The problem is this: definitions are complex (a definiens is always some combination of terms), so what accounts for the definiendum being *one* thing, rather than many (1037b10)? Man, for example, is defined as *rational animal*; “why is this one and not many — *rational* and *animal*?” (1037b13-14). Presumably, Aristotle has in mind his discussion in Z.4 of such “accidental unities” as a pale man. The difference cannot be that our language contains a single word (‘man’) for a rational animal, but no single word for a pale man, for

Aristotle has already conceded (1029b28) that we might very well have had a single term (he suggests *himation*, literally ‘cloak’) for a pale man, but that would still not make the formula ‘pale man’ a definition nor *pale man* an essence (1030a2).

Aristotle proposes a solution that applies to definitions reached by the “method of division.” According to this method (see Aristotle's logic), one begins with the broadest genus containing the species to be defined, and divides the genus into two sub-genera by means of some differentia. One then locates the definiendum in one of the sub-genera, and proceeds to divide this by another differentia, and so on, until one arrives at the definiendum species. This is a classic definition by genus and differentia. Aristotle's proposal is that “the division should be by the differentia of the differentia” (1038a9). For example, if one uses the differentia *footed* to divide the genus *animal*, one then uses a differentia such as *cloven-footed* for the next division. If one divides in this way, Aristotle claims, “clearly the last (or completing, *teleutaia*) differentia will be the substance of the thing and its definition” (1038a19). For each “differentia of a differentia” entails its predecessor (being cloven-footed entails being footed), and so the long chain of differentiae can be replaced simply by the last differentia. As Aristotle points out, “saying *footed two-footed animal* . . . is saying the same thing more than once” (1038a22-24).

This proposal shows how a long string of differentiae in a definition can be reduced to one, but it does not solve the problem of the unity of definition. For we are still faced with the apparent fact that genus + differentia constitutes a plurality even if the differentia is the last, or “completing,” one. It is not surprising, then, that Aristotle returns to the problem of unity later (H.4) and offers a different solution.

§10. Substances and Universals

At this point, we seem to have a clear idea about the nature of substantial form as Aristotle conceives of it. A substantial form is the essence of a substance, and it corresponds to a species. Since it is an essence, a substantial form is what is denoted by the definiens of a definition. Since only universals are definable, substantial forms are universals. That substantial forms are universals is confirmed by Aristotle's comment, at the end of Z.8, that “Socrates and Callias are different because of their matter . . . but they are the same in form” (1034a6-8). For them to be the same in form is for them to have the same form, i.e., for one and the same substantial form to be predicated of two different clumps of matter. And being “predicated of many” is what makes something a universal (*De Interpretatione* 17a37).

But Z.13 throws our entire understanding into disarray. Aristotle begins by returning to the candidates for the title of *ousia* introduced in Z.3, and points out that having now discussed the claims of the subject and the essence, it is time to consider the third candidate, the universal. But the remainder of the chapter consists of a barrage of arguments to the conclusion that universals are not substances.

Z.13 therefore produces a fundamental tension in Aristotle's metaphysics that has fragmented his interpreters. Some maintain that Aristotle's theory is ultimately inconsistent, on the grounds that it is committed to all three of the following propositions:

(i) Substance is form.

(ii) Form is universal.

(iii) No universal is a substance.

Others have provided interpretations according to which Aristotle does not maintain all of (i) - (iii), and there is a considerable variety of such interpretations, too many to be canvassed here. But there are two main, and opposed, lines of interpretation. According to one, Aristotle's substantial forms are not universals after all, but each belongs exclusively to the particular whose form it is, and there are therefore as many substantial forms of a given kind as there are particulars of that kind. According to the other, Aristotle's arguments in Z.13 are not intended to show that no universal is a substance, *tout court*, but some weaker thesis that is compatible with there being only one substantial form for all of the particulars belonging to the same species. Proponents of particular forms (or essences) include Sellars 1957, Harter 1975, Hartman 1977, Irwin 1988, Witt 1989b. Opponents include Woods 1967, Owen 1978, Code 1986, Loux 1991, Lewis 1991.

It would be foolish to attempt to resolve this issue within the confines of the present entry, as it is perhaps the largest, and most disputed, single interpretative issue concerning Aristotle's *Metaphysics*. I will, instead, mention some of the main considerations brought up on each side of this dispute, and give my reasons for thinking that substantial forms are universals.

The idea that substantial forms are particulars is supported by Aristotle's claims that a substance is “separate and some this” (*chôriston kai tode ti*, Z.3), that there are no universals apart from their particulars (Z.13), and that universals are not substances (Z.13). On the other side, the idea that substantial forms are universals is supported by Aristotle's claims that substances are, *par excellence*, the definable entities (Z.4), that definition is of the universal (Z.11), and that it is impossible to define particulars (Z.15).

In my opinion, the indefinability of particulars makes it impossible for substantial forms to be particulars. If there were a substantial form that is unique to some sensible particular, say Callias, then the definition corresponding to that form, or essence, would apply uniquely to Callias — it would define him, which is precisely what Aristotle says cannot be done. The question, then, is whether the evidence against substantial forms being universals can be countered. This is less clear, but the following considerations are relevant. (1) Aristotle's claim that a substantial form is an individual (*tode ti*) does not exclude its being a universal (*katholou*). Universals are contrasted with particulars (*kath' hekasta*), not individuals (although Aristotle does sometimes ignore the distinction between *tode ti* and *kath' hekaston*). What makes something a *tode ti* is its being a fully determinate thing, not further differentiable; what makes something a *kath' hekaston* is its being a particular thing, unrepeatable, and not predicated of anything else. There is thus the possibility of a universal *tode ti* — a fully determinate universal not further divisible into lower-level universals, but predicated of numerous particulars. (2) The claim that there are no universals apart from particulars needs to be understood in context. When Aristotle asserts (1038b33) that “there is no animal apart from the particulars (*ta tina*)” he is just as likely to be referring to the particular *kinds* of animals as he is to particular specimens. If so, his point may be that a generic kind,

such as animal, is ontologically dependent on its species, and hence on the substantial forms that are the essences of those species. (3) The arguments of Z.13 against the substantiality of universals are presented as part of a give-and-take investigation of the perplexities involved in the notion of substantial form. It is not clear, therefore, whether the blanket claim “No universal is a substance” is intended to be accepted without qualification. Indeed, a closer examination of the arguments may show that qualifications are required if the arguments are to be cogent. For example, the argument at 1038b11-15 is based on the premise that the substance of *x* is peculiar (*idion*) to *x*. It then draws the conclusion that a universal cannot be the substance of all of its instances (for it could not be *idion* to all of them), and concludes that it must be the substance “of none.” But note that this conclusion does not say that no universal can be a substance, but only that no universal can be the substance of any of its instances (cf. Code 1978). Aristotle's point may be that since form is predicated of matter, a substantial form is predicated of various clumps of matter. But it is not the substance of those clumps of matter, for it is predicated accidentally of them. The thing with which it is uniquely correlated, and of which it is the substance, is not one of its instances, but is the substantial form *itself*. This conclusion should not be surprising in light of Aristotle's claim in Z.6 that “each substance is one and the same as its essence.” A universal substantial form just is that essence.

§11. Substance as Cause of Being

In Z.17 Aristotle proposes a new point of departure in his effort to say what sort of a thing substance is. The new idea is that a substance is a “principle and a cause” (*archê kai aitia*, 1041a9) of being. Before looking at the details of his account, we will need to make a brief detour into Aristotle's theory of causes. The relevant texts are *Physics* II.3, *Posterior Analytics* II.11, and *Metaphysics* A.3 and Δ.2. See also the entries on [*Aristotle's physics*] and [Aristotle's psychology].

The word *aitia* (“cause” or, perhaps better, “explanation”), Aristotle tells us, is “said in many ways.” In one sense, a cause is “that out of which a thing comes to be, and which persists; e.g., bronze, silver, and the genus of these are causes of a statue or a bowl” (*Physics* 194b24). A cause in this sense has been traditionally called a *material* cause, although Aristotle himself did not use this label. In a second sense, a cause is “the form . . . the account of the essence” (194b27), traditionally called the *formal* cause. A third sense, traditionally called the *efficient* cause, is “the primary source of change or rest” (194b30). In this sense, Aristotle says, an adviser is the cause of an action, a father is the cause of his child, and in general the producer is the cause of the product. Fourth is what is traditionally called the *final* cause, which Aristotle characterizes as “the end (*telos*), that for which a thing is done” (194b33). In this sense, he says, health is the cause of walking, since we might explain a person's walking by saying that he walks in order to be healthy — health is what the walking is *for*. Note that, as in this case, “things may be causes of one another — hard work of fitness, and fitness of hard work — although not in the same sense: fitness is what hard work is for, whereas hard work is principle of motion” (195a10). So hard work is the efficient cause of fitness, since one becomes fit by means of hard work, while fitness is the final cause of hard work, since one works hard in order to become fit.

Although Aristotle is careful to distinguish four different kinds of cause (or four different senses of

‘cause’), it is important to note that he claims that one and the same thing can be a cause in more than one sense. As he puts it, “form, mover, and *telos* often coincide” (198a25). And in *De Anima* he is perfectly explicit that the soul, which is the form or essence of a living thing, “is a cause in three of the ways we have distinguished” (415b10) — efficient, formal, and final.

Let us return to Aristotle's discussion in Z.17. The job of a cause or principle of being, he notes, is to explain why one thing belongs to another (1041a11); that is, it is to explain some predicational fact. What needs to be explained, for example, is why *this is a man*, or *that is a house*. But what kind of a question is this? The only thing that can be a man is a man; the only thing that can be a house is a house. So we would appear to be asking why a man is a man, or why a house is a house, and these seem to be foolish questions that all have the same answer: because each thing is itself (1041a17-20). The questions must therefore be rephrased by taking advantage of the possibility of a hylomorphic analysis. We must ask, e.g., “Why are these things, i.e., bricks and stones, a house?” (1041a26). The answer Aristotle proposes is that the cause of being of a substance (e.g., of a house) is the form or essence that is predicated of the matter (e.g., of the bricks and stones) that constitute that substance. The essence is not always just a formal cause; in some cases, Aristotle says, it is also a final cause (he gives the examples of a house and a bed), and in some cases an efficient cause (1041a29-30). But in any case “what we seek is the cause, i.e., the form, by reason of which the matter is some definite thing; and this is the substance of the thing” (1041b6-9) and “the primary cause of its being” (1041b27).

Notice that the explanandum in these cases (“why is this a man?” or “why is that a house?”) involves a species predication (“Callias is a man,” “Fallingwater is a house”). But the answer Aristotle proposes invokes a hylomorphic analysis of these questions, in which form is predicated of matter. So Callias is a man because the form or essence of man is present in the flesh and bones that constitute the body of Callias; Fallingwater is a house because the form of house is present in the materials of which Fallingwater is made. In general, a species predication is explained in terms of an underlying form predication, whose subject is not the particular compound but its matter. Form predications are thus more basic than their corresponding species predications. A substantial form, as a primary definable, is its own substance, for it is essentially predicated of itself alone. But the substantial form of a material compound, because it is predicated (accidentally) of the matter of the compound, is the cause of the compound's being the kind of thing that it is. The form is therefore, in a derivative way, the substance of the compound, as well.

§15. Glossary of Aristotelian Terminology

- Accident: *sumbebêkos*
- Accidental: *kata sumbebêkos*
- Account: *logos*
- Actuality: *energeia*, *entelecheia*
- Alteration: *alloiôsis*
- Affirmative: *kataphatikos*
- Assertion: *apophansis* (sentence with a truth value, declarative sentence)

- Assumption: *hupothesis*
- Attribute: *pathos*
- Axiom: *axioma*
- Be: *einai*
- Being(s): *on*, *onta*
- Belong: *huparchein*
- Category: *katêgoria*
- Cause: *aition*, *aitia*
- Come to be: *gignesthai*
- Coming to be: *genesis*
- Contradict: *antiphanai*
- Contradiction: *antiphasis* (in the sense “contradictory pair of propositions” and also in the sense “denial of a proposition”)
- Contrary: *enantion*
- Definition: *horos*, *horismos*
- Demonstration: *apodeixis*
- Denial (of a proposition): *apophasis*
- Dialectic: *dialektikê*
- Differentia: *diaphora*; specific difference, *eidopoios diaphora*
- Distinctive: *idios*, *idion*
- End: *telos*
- Essence: *to ti ên einai*, *to ti esti*
- Essential: *en tôi ti esti*, *en tôi ti ên einai* (of predications); *kath' hauto* (of attributes)
- Exist: *einai*
- Explanation: *aition*, *aitia*
- Final cause: *hou heneka* (literally, “what something is for”)
- Form: *eidos*, *morphê*
- Formula: *logos*
- Function: *ergon*
- Genus: *genos*
- Homonymous: *homônumon*
- Immediate: *amesos*
- Impossible: *adunaton*
- In respect of itself: *kath' hauto*
- Individual: *atomon*, *tode ti*
- Induction: *epagôgê*
- Infinite: *apeiron*
- Kind: *genos*, *eidos*
- Knowledge: *epistêmê*
- Matter: *hulê*
- Nature: *phusis*
- Negation (of a term): *apophasis*
- Particular: *en merei*, *epi meros* (of a proposition); *kath'hekaston* (of individuals)

- Peculiar: *idios, idion*
- Per se: *kath' hauto*
- Perception: *aisthêsis*
- Perplexity: *aporia*
- Possible: *dunaton, endechomenon*; *endechesthai* (verb: "be possible")
- Potentially: *dunamei*
- Potentiality: *dunamis*
- Predicate: *katêgorein* (verb); *katêegoroumenon*("what is predicated")
- Predication: *katêgoria* (act or instance of predicating, type of predication)
- Principle: *archê* (starting point of a demonstration)
- Qua: *hêi*
- Quality: *poion*
- Quantity: *poson*
- Refute: *elenchein*; refutation*, elenchos*
- Separate: *chôriston*
- Said in many ways: *pollachôs legetai*
- Science: *epistêmê*
- Soul: *psuchê*
- Species: *eidos*
- Specific: *eidopoios* (of a differentia that "makes a species", *eidopoios diaphora*)
- Subject: *hupokeimenon*
- Substance: *ousia*
- Term: *horos*
- This: *tode ti*
- Universal: *katholou* (both of propositions and of individuals)
- Wisdom: *sophia*

Supplement to Aristotle's Metaphysics

Nonsubstantial Particulars

The precise nature of particulars in nonsubstance categories has been, and remains, a matter of considerable controversy. According to the traditional account (cf. Ackrill 1963), by “the particular white” (or “a certain white”, *to ti leukon*) Aristotle means a *trope*, something that is unique to the individual substance in which it inheres and is not repeatable elsewhere. If a particular white is in Socrates, then it is not in anything else. Indeed, even if Callias is of exactly the same shade of color as Socrates, the particular white in Callias is an entity distinct from the particular white in Socrates — they are two numerically distinct but qualitatively identical tropes. An alternative account (initially championed by Owen 1965a) takes “the particular white” to denote a repeatable entity: a fully determinate universal that is capable of being shared by distinct substances. It is only a particular in the sense that it is not essentially predicated (‘said of’) anything else in its own category. That is, a particular white is a fully determinate shade of color, rather than a determinable such as *white*, which is a generic classification of various determinate shades of white.

At the center of the controversy is the interpretation of Aristotle's definition of ‘in’. At *Cat*. 1a25 he says “by ‘in a subject’ I mean what is in something, not as a part, and cannot exist separately from what it is in.” The definition is clearly ambiguous. On the one hand, it might mean that what is ‘in’ a particular subject is incapable of existing separately from that subject. This is Ackrill's understanding:

> x is in $y =_{\mathrm{df}}$
>
> > (a) x belongs to y, and
> > (b) x is not a part of y, and
> > (c) x cannot exist separately from y.

On this understanding, the only thing that can, strictly speaking, be ‘in’ a particular subject (e.g., Socrates) is something that cannot exist separately from that subject. The color ‘in’ Socrates, in this sense, could not exist ‘in’ anything else. Indeed, the only thing that can be ‘in’ a particular substance, in this sense, is something that cannot exist separately from that substance.

The problem for this reading of Aristotle's definition is that specific or generic universals (such as *white* and *color*) could not be ‘in’ a particular substance; *color* could not be ‘in’ Socrates because *color* can surely exist separately from Socrates. Yet Aristotle says (2b2) that “color is in body, and therefore in an individual body (for if it were not in any individual, it would not be in body at all).” Unless Aristotle is speaking carelessly here (as Ackrill supposes), his claim cannot be consistent with the definition of ‘in’,

as Ackrill interprets it.

A second reading of Aristotle's definition is Owen's:

> *x* is in *y* $=_{\text{df}}$
>
> > (a) *x* belongs to *y*, and
> > (b) *x* is not a part of *y*, and
> > (c) *x* cannot exist on its own (i.e., *x* cannot exist unless there is something *z* such that *x* belongs to *z*)

On this understanding, it is possible for a generic quality, such as *white* or *color*, to be ‘in’ a particular substance. The reason that *white* can be ‘in’ Socrates (as well as in other individuals) is that *white* belongs to (i.e., is a property of) Socrates, not a part of him, and is incapable of existing unless it belongs to some substance or other.

A third reading of Aristotle's definition is that of Frede 1987:

> *x* is in a subject $=_{\text{df}}$
>
> > There is something, *y*, such that
> > (a) *x* is not a part of *y*, and
> > (b) *x* cannot exist independently of *y*.

Frede's reading is different from the other two in one important way, yet shares features of each. The difference is that on Frede's reading Aristotle is defining the one-place predicate ‘*x* is in a subject’, not the two-place predicate ‘*x* is in *y*’. That is, he is defining what it is to be an *accident*, the sort of thing that is ‘in’ a subject, rather than what it is for *x* to be ‘in’ *y*. This reading, like Owen's, allows a generic quality, such as *white* or *color*, to be ‘in’ a particular substance. *White* can be ‘in’ Socrates because it is an accident (i.e., it is an ‘in a subject’ sort of thing) and belongs to (i.e., is a property of) Socrates. Yet, like Ackrill's, it has a specific “inseparability” requirement. That is, in order for *x* to be an accident, there must be some sort of thing that *x* is incapable of existing separately from. In the case of *color*, that thing is *body*.

There is a vast literature on this dispute. See, in addition to Ackrill and Owen: Matthews and Cohen 1968, Allen 1969, Duerlinger 1970, Jones 1972, Annas 1974, Hartman 1977, Granger 1980, Heinaman 1981a, Frede 1987, Matthews 1989, Devereux 1992, and Wedin 1993.

Tropes

A trope is an instance or bit (not an exemplification) of a property or a relation; e.g. Clinton's eloquence, Sydney's beauty, or Pierre's love of Heloïse. Clinton's eloquence is understood here not as Clinton's participating in the universal eloquence, nor as the peculiar quality of Clinton's eloquence, but simply as Clinton's bit of eloquence, the eloquence that he and he alone has. Similarly, Pierre's love is not his participation in love as such, nor the special way he loves, but the loving peculiar to Pierre as directed toward Heloïse. The appeal of tropes for philosophers is as an ontological basis free of the postulation of obscure abstract entities such as propositions and universals.

Name and Incidence in Philosophy

The ontological theory of tropes holds that properties and relations subsist as so many instances or tropes, one for each exemplification. These tropes are particulars, not universals, distinct from the concrete particulars they characterize. By other names, trope ontologies have been espoused throughout the history of Western philosophy. According to D. W. Mertz (1996, ch. IV), variants can be found in the writings of Plato, Aristotle, Boëthius, Avicenna, Averroës, Thomas, Scotus, Buridan, Suárez, Leibniz, Husserl, the early Russell (1911), Stout, Cook Wilson, and Strawson. Tropes have been variously called "property (and relation) instances", "abstract particulars", "concrete properties", "unit properties (and relations)", "quality (and relation) bits", "individual accidents", and (in German) "*Momente*".

(Parenthesized years refer to the Bibliography below.)

The most compelling advocate of such objects in our time has been D. C. Williams (1953), who is responsible for the regrettable term *trope*. It has nothing to do with figures of speech in rhetoric, *Leitmotive* in music, or tropisms in plants. Williams coined it as a sort of philosophical joke: Santayana, he says, had employed ‘trope’ pointlessly for ‘essence of an occurrence’. Williams would go him one better and press it into service for ‘occurrence of an essence’ (1953: 78). [Far from poking fun at Santayana, Williams published an appreciation of his views on essence and occurrence in a memorial issue of the *Journal of Philosophy* (1954).] Ironically, the word ‘trope’ is to be heard correctly these days mainly from the lips of poststructuralists. Meanwhile, many trope theorists have adopted Williams’ usage, but some avoid it (e.g. Mertz). Williams acknowledged the close affinity between his trope theory and G. F. Stout’s theory of abstract particulars (1921, 1923).

Approaches to Univerals

Obviously one could see tropes as complexes of some sort, perhaps composed of particulars and universals. (I use ‘universal’ here to cover both properties and relations.) Such a construction is, indeed, very strongly suggested by the subject-predicate form of our language. Philosophical ontologists have, however, long since considered departing from this linguistic pattern in various ways. Nominalists recognize the particulars as subjects, but hold that there really are no universals beyond the linguistic predicates themselves. Plato held, by contrast, that certain universals, the Forms, are the only realities, the particulars being mere figments of belief (-380). A less radical variant of nominalism recognizes properties and relations, but as mere set-theoretic constructs out of individuals. This approach is usual in model-theoretic semantics. A less otherworldly version of Platonism takes particulars to be bundles of universals; cf. Russell (1940, ch. 6, 8, 24) and Blanshard (1939, ch. 16, 17). For those students of ontology who are not obsessed with parsimony, however, the most natural course would probably seem to be to take a leaf from our language and to recognize both exemplifying individuals and repeatedly exemplified universals. Such a view is so common that it has no particular name; Armstrong calls it the "substance-attribute view" (1989: 59 et seq.). This view need not deny that there are tropes, but it denies that they are basic or simple or primitive. Rather they must be composite structures involving a property or relation, some individuals, and an exemplification nexus. An ontology based on tropes takes the opposite approach. It recognizes tropes as basic, not as constructed. Individuals and properties then require further analysis. Ontological theories thus based on primitive tropes may be called versions of tropism or trope theory. A major attraction of tropism has been its promise of parsimony; some adherents go so far as to proclaim a one-category ontology (Campbell, Mertz).

Varieties of Trope Theory

Trope theories divide according to their treatment of universals and individuals. What I should like to regard as the classic trope theory (Stout, Williams) treats universals and individuals as constructs or bundles of tropes. This is the trope-bundle theory, called by some (Simons, Mertz) trope nominalism or

moderate nominalism (Hochberg). (‘Nominalism’ because it repudiates primitive universals; ‘moderate’ because it still recognizes unit properties). Then there are trope theories that retain either primitive individuals or primitive universals. The former position, substratum tropism, was taken in a way by Leibniz, who recognized individual substances (monads), but correlated with complete individual concepts comprising nonrelational tropelike representations of the whole world (1686: §§9, 14; 1714: §§8, 14, 17-19). A similar view is hailed by C. B. Martin (1980) in Locke (1690: 159) and noted approvingly by Armstrong (1989: 114, 136). The latter view, tropes plus primitive universals, was held by Cook Wilson (1926, vol. 2, 713 *et passim*) and may be represented also by Mertz (1996), with the important qualification that his universals are given conceptual, not Platonic status. Such a position might be called trope universalism; Mertz calls his version "moderate realism". (‘Realism’ because universals are recognized; ‘moderate’ because they are immanent: only their instances really exist.) Finally, there is the possibility of combining tropism with a full substance-attribute view. Husserl (1913-21: 430f, 436f) may perhaps be read in this way, and certain truthmaker theories may come close. (Truthmakers, like tropes, may be posited in addition to states of affairs, complexes made up of particulars and universals.)

Another significant division among trope theories separates the actualists from the meinongians. (The term alludes to no specific teaching of Meinong, just the preparedness to recognize nonexistents.) For the actualist, there is a trope, say, of Old Faithful’s heat, only if Old Faithful is actually hot. The only property instances are actual ones. For the meinongian, on the other hand, there are also tropes of Old Faithful’s coldness, Bill Clinton’s shyness, etc. (The contrast mirrors the traditional dispute over false facts or nonobtaining states of affairs.) These days actualism is popular. Meinongian tropism has, however, one great advantage: it affords a straightforward account of possible worlds (deemed by many hopelessly obscure). A possible world, on this approach, is simply a set of tropes. (There are problems with nonlogically incompatible tropes, such as *a*’s redness and *a*’s greenness, but similar problems beset other theories. Not every trope set need be a possible world.)

Trope-Bundle Theory

Classic tropism, the trope-bundle theory, would seem to hold the greatest promise of economy. For this theory dispenses with both primitive individuals and primitive universals, leaving at first glance only tropes. However, second-level bundling relations of tropes prove necessary. Tropes belong to the same individual if they are all *compresent* (concurrent) with one another. Tropes belong to the same universal (property or relation) if they *exactly resemble* one another. The two second-level trope relations of compresence and exact resemblance are essential to the bundle theory. They are similarity relations (reflexive and symmetric); compresence is also transitive, an equivalence relation on tropes. Thus universals become similarity classes and individuals equivalence classes of tropes: both are products of abstraction. (This is a first approximation: individuals may ultimately have be taken as more complicated; see Individuals Refined.) Exemplification (as expressed by predication) is then simply overlapping. On the actualist approach, Clinton is eloquent iff he (his compresence class) overlaps eloquence (the set of eloquences). The meinongian approach brings in possible worlds: Clinton is eloquent in *w* iff he, eloquence, and *w* all overlap.

Trope-bundle theory can be further developed to include a treatment of compound universals (also requiring further complications in the structure of individuals and universals) and a construction of what Bacon calls states of affairs (essentially, world sets) (1995, ch. III). The whole question of the relation of tropes to states of affairs is a vexed one, partly because intuitive conceptions of states of affairs diverge. For some, it is analytic that states of affairs are complexes, making it unthinkable for them to be tropes. Others see an extensive parallel between the two notions. The latter view is ruled out if the tropes are assumed as basic. But there is some interest in seeing what results if we plug states of affairs (complexes) into trope theory in place of tropes. Connections both to situation semantics and to Armstrong's later theory of universals (1989: 94) are revealed.

Relations

The seemingly parsimonious trope-bundle theory, as we saw, is pushed to acknowledge at least a second category besides tropes, the second-level relations. There are probably more such relations, e.g. temporal precedence and betterness. Williams advocated the obvious therapy here without working out the details. The second-level relations, he suggested, crumble into second-level tropes (1953: 84). But it should be clear that in order to bundle second-level tropes into the requisite relations, *third*-level relations will be needed, and so forth. It turns out that a significant simplification is actually achieved at the third or fourth level, so the regress is not vicious. At least one unpulverized relation is still needed though, and the third- or fourth-level tropes ultimately assumed are scarcely plausible candidates for basic constituents of reality.

Mertz points out how hostile the Western tradition has been to recognizing genuine relations (1996, ch. 6). Only Russell's early insistence on their importance turned the tide in our century. Few trope theories have a well worked out treatment even of first-level (ordinary) relations. Campbell holds that while relational *discourse* is ineliminable, relations themselves come down to their *foundations*, the properties of their relata in which they are grounded (1990: 98ff). As Mertz has pointed out (1996: 63-67), this general approach goes back at least as far as Ockham. Although Campbell does not give details, the project is not to be regarded as hopeless.

Bacon, on the other hand, retains first-level relations in the same status as properties, bundled into universals by exact resemblance (1995, ch. II). But whereas modern predicate logic treats the semantic values of relational predicates as complicated (as sets of *n*-tuples), Bacon complicates individuals. He multiplies compresence into indexed 1-compresence, 2-compresence, . . . An individual (in the new extended sense) is then a chain (sequence) of a 1-compresence-equivalence class, a 2-compresence-equivalence class, and so on. This inobvious extension makes a unified treatment of predication possible. On the actualist approach, Yeltsin is healthy iff his first compresence class overlaps health. Pierre loves Heloïse iff his first compresence class, her second compresence class, and love all overlap. The meinongian approach brings in possible worlds: Yeltsin is healthy in *w* iff his 1-compresence class, health, and w all overlap. The dyadic case is similar. Williams considered the explication of exemplification to be one of the important achievements of tropism, "do[ing] much to dispel the ancient mystery of predication" (1953: 82). Bacon extends that explication to relational predication.

Individuals Refined

For some trope theorists, a mere set of tropes, or even a chain of such, has too little inner coherence and unity to qualify as an individual. Thus Williams takes an individual to be the *mereological sum* of a compresence class (1953: 81). Martin writes, "An object is not a collectable out of its properties or qualities as a crowd is collectable out of its members. For each and every property of an object has to be had by that object to exist at all" (1980: 8). Mertz constructs individuals with the help of what he calls integrated networks (1996: 76). The integrated network of a particular *t* comprises all the atomic facts about *t.* Since the integrated network is itself a nonrepeatable individual, it can have its own integrated network, and so on. A hierarchy of such integrated networks is then an ordinary individual. Mertz appears to leave it open whether the hierarchy ever terminates. He is also vague about facts (states of affairs): they are complexes consisting of a trope and its exemplification or relata, the latter apparently also tropes. Facts serve as truthmakers. Mertz's account is developed partly to avoid positing individuals as bare particulars. The price would seem to be to obscure the truth condition for simple predication sentences.

A further refinement of bundles is offered in Simons' nuclear theory (1994). In place of compresence, Simons takes over Husserl's foundation relation (1913-22.478f). A trope s is *founded* on *t* if *t*'s existence is necessary for the existence of *s. s* and *t* are *directly foundationally related* if either is founded on the other. *Foundational relatedness*, the ancestral of direct foundational relatedness, is an equivalence relation on tropes. Its equivalence classes are *foundational systems.* An *integral whole* [Husserl: whole in the pregnant sense (1913-22.475)] is the mereological fusion of a foundational system. An integral whole forms the *nucleus* or individual nature of a substance. Its *accidents* are a nimbus of tropes dependent (founded) on the nucleus, generically though not individually required by it. Thus Simons envisions a tight bundle within a loose bundle, the whole constituting a thick particular. The tight bundle (the nucleus) is like a substratum, but is not assumed as basic.

Objections to the Bundle Theory

The assault on the trope-bundle theory has been led by Mertz. His objections appear to stem from two deeply held intuitions, which I will call the *predication intuition* and the *glue intuition.* According to the former, it is unacceptable to conceive of tropes as free-floating (Mertz 1996.26). They are not genuine property instances unless they are saturable, properties of something. Compresence classes do not possess enough unity to be genuine subjects of predication. At the same time, as we have seen, Mertz hesitates to posit primitive individuals lest they turn out to be bare particulars, which would be incoherent by his lights. Hence his hierarchies of integrated networks of tropes (see previous section).

According to the glue intuition, complexes need to be held together, and relations are the glue. They are "ontoglial", Mertz says, i.e., from the Greek, the glue of being (1996: 25). Sets and bundles as such lack unity. Thus Mertz is obliged to reject the bundle theory of relations as well as that of individuals. Only

genuine relations can be ontoglial. Together with the predication intuition, this yields Mertz's distinctive dualism about relations, his trope universalism or moderate realism. The basic universals do the gluing, but the basic tropes get predicated. What is the connection between the two? They are both aspects of the trope, the relation instance. The instance aspect is the fundamental ontic unit; the repeatable aspect is conceptual. It might seem that this makes the glue unreal, but Mertz speaks also of extra-conceptual intensions (universals) as goals of total science (1996: 32).

D. H. Mellor, citing Ramsey (1931), and Thomas Hofweber have objected that the above tropist account of predication in terms of overlapping makes exemplification symmetric: it fails to explain which is the subject and which is the the predicate, or which is the individual and which is the universal. So long as compresence classes can be distinguished from exact-resemblance classes (particulars from universals), there is no problem. But what if the same class could be both a particular (or a link in its bundle chain) and a universal? Bacon rules out this possibility, but seemingly *ad hoc*. Might it not be, for example, on a radically monotheistic scheme, that the trope God's divinity was the sole trope in the individual God as well as the sole trope in the property of divinity?

Applications of Trope Theory

Various applications have been proposed for trope theory. Campbell suggests that tropes are the natural relata of causation (1981: 480f). Although events are often cast in that role, Williams affirms that they are a kind of trope (1953: 90). It remains to see whether this insight will shed any real light on the nature of causation. [Bacon sketches a treatment of causation in trope theory, but it is not clear that he makes any essential use of tropes, other than to form possible worlds (1995, ch. VIII).] Campbell further suggests that tropes are the natural subjects of evaluation (1981: 481). Again, while this seems feasible, it is not clear where it takes us. [Bacon tries to develop this idea too (1995, ch. IX), but his treatment would seem to work equally well with states of affairs rather than tropes.] Campbell suggests a trope-theoretic interpretation of the fields recognized by modern physics, but a lot is expected of his field-tropes. Why not have just *one* trope, the-world's-being-the-way-it-is?

Mertz puts forward a distinctive system of logic, particularized predicate logic (PPL), exploiting the opportunity of quantifying over tropes in many places where we should expect second-order quantification over properties (1996, ch. IX). Impressive claims are made for PPL. It is said to be a provably consistent type-free extension of second-order logic, admitting impredicative definitions. Diagonal arguments and Gödel's incompleteness proofs are allegedly defeated, and solutions are proffered to Russell's paradox, the various liar paradoxes, and the generalized Fitch-Curry paradox.

While tropism, like any other theory, must stand or fall on its merits, it may be asking too much to expect metaphysical arguments to establish its pre-eminence. The substance-attribute view, the property-bundle theory, the trope-bundle theory, and even perhaps model-theoretic particularism are apparently all capable of modeling each other (Bacon 1988). If tropes deserve first place in first philosophy, it may be for epistemological or even pragmatic reasons. As we knock about the world, it is tropes we encounter in the first instance. An intelligible theory can start there.

Properties

Questions about the nature and existence of properties are nearly as old as philosophy itself. Interest in properties has ebbed and flowed over the centuries, but they are now undergoing a resurgence. The last twenty five years have seen a great deal of interesting work on properties, and this entry will focus primarily on that work (thus taking up where Loux's (1972) earlier review of the literature leaves off).

When we turn to the recent literature on properties we find a confusing array of terminology, incompatible standards for evaluating theories of properties, and philosophers talking past one another. It will be easier to follow this literature if we begin by focusing on the *point* of introducing properties in the first place. Philosophers who argue that properties exist almost always do so because they think properties are needed to solve certain philosophical problems, and their views about the *nature* of properties are strongly influenced by the problems they think properties are needed to solve. So the discussion here will be organized around the tasks properties have been introduced to perform and the ways in which these tasks influence accounts of the nature of properties.

In §1 I introduce some distinctions and terminology that will be useful in subsequent discussion. The tasks properties are called on to perform are typically *explanatory*, and so §2 contains a brief discussion of explanation in ontology. §3 contains a discussion of traditional attempts to use properties to explain phenomena in metaphysics, epistemology, philosophy of language, and ethics. §4 focuses on the three areas where contemporary philosophers have offered the most detailed accounts based on properties: philosophy of mathematics, the semantics of natural languages, and topics in a more nebulous area that might be called *naturalistic ontology*. We then turn to issues about the nature of properties, including their existence conditions (§5), their identity conditions (§6), and the various sorts of properties there might be (§7). §8 provides an introductory, informal discussion of formal theories of properties. After §2 the sections, and in many cases the subsections, are relatively modular, and readers can use the detailed tables of contents and hyperlinks to locate those topics that interest them most.

---

1 Distinctions and Terminology

1.1 Properties: Basic Ideas

Properties include the attributes or qualities or features or characteristics of things. Issues in ontology are so vexed that even those philosophers who agree that properties exist often disagree about *which* properties there are. This means that there are no wholly uncontroversial examples of properties, but likely candidates include the color and rest mass of the apple on my desk, as well (more controversially) as the properties of *being an apple* and *being a desk*. For generality we will also take properties to include relations like *being taller than* and *lying between*.

Universals and Particulars. A fundamental question about properties--second only in importance to the question whether there are any--is whether they are universals or particulars. To say that properties are universals is to say that the selfsame property can be instantiated by numerically distinct things. On this view it is possible for two different apples to exemplify exactly the same color, a single universal. The competing view is that properties are just as much individuals or particulars as the things that have them. No matter how similar the colors of the two apples, their colors are numerically distinct properties, the redness of the first apple and the redness of the second. Such individualized properties are variously known as ‘perfect particulars’, ‘abstract particulars’, ‘quality instances’, ‘moments’, and ‘tropes’. Tropes have various attractions and liabilities, but since they are the topic of another entry, we will construe properties (save for any, perhaps those like *being identical with Socrates*, that could only be exemplified by one thing) as universals.

Properties and Relations. Properties are sometimes distinguished from relations. For example, a specific shade of red or a rest mass of 3 kilograms is a property, while *being smaller than* or *having a weight of 29.4 newtons* are typically regarded as relations (both of which relate my laptop computer to the Earth). Relations generate a few special problems of their own, but for the most part properties and relations raise the same philosophical issues and, except where otherwise noted, I will use ‘property’ as a generic

term to cover both monadic (one-place, nonrelational) properties and (polyadic, multi-place) relations.

Properties can be Instantiated. Properties are most naturally contrasted with particulars, i.e., with individual things. The fundamental difference between properties and individuals is that properties can be *instantiated* or *exemplified*, whereas individuals cannot. Furthermore, at least many properties are *general*; they can be instantiated by more than one thing.

The things that exemplify a property are called *instances* of it (the instances of a relation are the things, taken in the relevant order, that stand in that relation). It is a matter of controversy whether properties can exist without actually being exemplified and whether some properties can be exemplified by other properties (in the way, perhaps, that *redness* exemplifies the property of *being a color*). Some philosophers even hold that there are unexemplifiable properties, e.g., *being red and not red*, but even they typically believe that such properties are intimately related to other properties (here *being red* and *not being red*) that can be exemplified.

Realism, Nominalism, and Conceptualism. The deepest question about properties is whether there are any. Textbooks feature a triumvirate of answers: *realism*, *nominalism*, and *conceptualism*. There are many species of each view, but the rough distinctions come to this. Realists hold that there are universal properties. Nominalists deny this (though some hold that there are tropes). And conceptualists urge that words (like ‘honesty’) which might seem to refer to properties really refer to concepts. A few contemporary philosophers have defended conceptualism (cf. Cocchiarella, 1986, ch. 3), and recent empirical work on concepts bears on it. It is not a common view nowadays, however, and I will focus on realism here.

The Revival of Properties. Just a few decades ago many philosophers concurred with Quine's dismissal of properties as "creatures of darkness," but philosophers now widely invoke them without guilt or shame. For example, most current discussions of mental causation are couched in terms of the causal efficacy of mental properties, while discussions of supervenience often proceed by way of a claim that one family of properties (e.g., mental properties) is supervenient on some other family of properties (e.g., physical properties). But the resurgence of interest in properties has left us with widely varying accounts of their nature, and questions about their existence have by no means disappeared.

Properties are as Properties Do. It is possible to classify theories of properties in terms of their characterizations of the *nature* of properties *or* in terms of the *jobs* they introduce properties to do. The former kind of characterization is more fundamental, but since views about the nature of properties are typically motivated by accounts of the work properties are invoked to do, it will be more useful to begin with the latter. We will ask what *explanatory roles* properties have been introduced to fill, and we will then try to determine what something would *have* to be *like* in order to occupy those roles. This will also allow us to consider the sorts of arguments that are typically advanced for the claim that properties exist.

1.2 Talking about Properties

Philosophers do not have a settled idiom for talking about properties. Often they make do with a simple distinction between singular terms and predicates. Singular terms are words and phrases (like proper names and definite descriptions) that can occupy subject positions in sentences and that purport to denote or refer to a single thing. Examples include ‘Bill Clinton,’ ‘Chicago’, and ‘The first female Supreme Court Justice’. Predicates, by contrast, can be true of things. When we represent a sentence like ‘Quine is a philosopher’ in a standard formal language (like first-order logic) as ‘*Pq*’, we absorb the entire expression ‘is a philosopher’ into the predicate ‘*P*’ (though for some theoretical purposes it is more useful to count ‘philosopher’ or even ‘a philosopher’ as the predicate). The notion of a predicate is supplanted by the notion of a verb phrase in modern grammars, so we don't need to pursue this issue here, but we can raise our first question about property talk at this relatively atheoretical level.

Failed Substitutions

It is perfectly grammatical to say ‘Monica is honest’ or ‘Honesty is a virtue’, but your old English teacher will cringe if you say ‘Honest is a virtue’ or ‘Monica is honesty’. We must use ‘honest’ after the ‘Monica is’, and we have to use the nominalization, ‘honesty’, before ‘is a virtue’. The fact that ‘honest’ and ‘honesty’ cannot be interchanged without destroying the grammaticality of our original sentences has been thought to have various philosophical morals. Some philosophers take it to show that the two expressions cannot stand for the same thing; for example, ‘honest’ might stand for a property and ‘honesty’ might stand for a property-correlate of some sort (Frege draws roughly this moral from his discussion of ‘the concept horse’). Others take it to show that although both expressions are related to the same thing, the property *honesty*, they are related to by different semantic relations; for example, the nominalization denotes this property, whereas the predicate expresses it.

Frege's argument for the first sort of view is not compelling (see Parsons, 1986, for a good discussion); moreover, it would be desirable to avoid multiplying entities (e.g., property correlates) and semantic relations (e.g., expression) beyond necessity. And mere failures of substitutivity are not enough to show that they are necessary, since various syntactic features of sentences prohibit the exchange of terms that are clearly co-referential. Consider case forms of personal pronouns: ‘I’ and ‘me’ cannot be exchanged (without destroying grammaticality) in sentences like ‘*I* dropped the hammer, and he returned it to *me*’. But no one concludes that distinct objects (me and a me-correlate) or distinct semantic relations (nominative-case reference and accusative-case reference) are needed to account for this.

Predicative Expressions

The multiplicity of ways of talking about properties can be obscured when we use familiar formal languages to represent them. The constructions verb (‘lives’), verb + adverb (‘sings badly’), copula + adjective (‘is red’), copula + determiner + common noun (‘is a dog’), copula + noun phrase (‘is a Republican President), and (if Davidson's account of events is correct) even adverbs (‘slowly’) and prepositional phrases (‘in the bathroom’) all go over into the familiar ‘*F*’s and ‘*G*’s of standard logical notation. The fact that these expressions can often be handled in the same way without too much violence tells us that they have certain similarities, but there are also many differences, and some of them may turn out to be relevant to ontology.

Singular Terms

The complexities involving property words are even greater when we turn to singular terms. We can form singular terms from predicative expressions in many ways (different ways are appropriate for different predicates). To begin with, English contains a plethora of *suffixes* that we can append to predicative expressions (sometimes after minor surgery on the original) to form singular terms. These include '-hood' ('motherhood, 'falsehood), '-ness' ('drunkeness', 'betweeness'), '-ity' ('triangularity', 'solubility', 'stupidity'), '-kind' ('mankind'), '-ship' ('friendship', 'brinksmanship'), 'ing' ('walking', 'loving'), 'ment' ('commitment', 'judgment'), 'cy' ('decency', 'leniency'), and more.

Various philosophical terms of art serve a similar purpose. The word 'itself' plays this role in some translations of Plato ('The equal itself', 'Justice itself'), and contemporary authors use phrases like 'the property red', 'the property of being red', and 'the causal relation' to much the same end. Various gerundive phrases (e.g., 'being red' and 'being a red thing') and infinitive phrases ('to be happy', 'to be someone who is happy') work in a similar way. Finally, there are many less systematic ways of talking about properties; for example, we can use a definite description that a property just happens to satisfy ('the color of my true love's hair', 'John's favorite four-place relation').

The expressions formed in these ways occupy subject positions in sentences where they seem to denote to properties. It is worth noting, however, that it is often impossible to substitute some of these expressions for related ones without destroying the grammaticality or, in some cases, without altering the truth value of the original sentence. Consider 'wisdom', 'being wise', 'the property of being wise', and 'to be wise'. 'Wisdom is a virtue' is unexceptionable, but 'Being wise is a virtue' is shaky at best. On the other hand, 'To be wise is to be virtuous' and 'Being wise is a good thing' are fine, but 'Wisdom is to be virtuous' clearly won't do. And 'The property of being wise is a good thing' is grammatical, but has a different meaning from 'Being wise is a good thing'.

The phenomenon of case shows that lack of substitutivity alone doesn't have deep ontological consequences, but it is quite possible that the sorts of phenomena noted in the previous paragraph signal important differences in ontology. Some of these differences might begin to emerge from informal probing, but we cannot expect to settle such matters without detailed, philosophically-sensitive syntactic and semantic theories that are better supported than their rivals. Such theories do not yet exist, and so here I will be fairly cavalier about "property terms," using various phrases, e.g., 'redness' and 'the property of being red' indifferently to refer to the same property. But this expedient is not meant to suggest that subtle grammatical differences won't eventually turn out to have important ontological implications.

2 Philosophical Explanations: Why Think that Properties Exist?

2.1 Explanation in Ontology

Properties are typically introduced to help *explain* or *account for* phenomena of philosophical interest. The existence of properties, we are told, would explain qualitative recurrence or help account for our ability to agree about the instances of general terms like 'red'. In the terminologies of bygone eras, properties save the phenomena; they afford a *fundamentum in re* for things like the applicability of general terms. Nowadays philosophers make a similar point when they argue that some phenomenon holds *because of* or *in virtue of* this or that property, that a property is its *foundation* or *ground* for it, or that a property is the *truth maker* for a sentence about it. These expressions signify explanations.

When properties are introduced to help explain certain philosophically puzzling phenomena, we have a principled way to learn what properties are *like*: since they are invoked to play certain *explanatory roles*, we can ask what they would *have* to be like in order to play the roles they are introduced to fill. What, for example, would their existence or identity conditions need to be for them to explain the (putative) modal features of natural laws or the *a priori* status of mathematical truths?

The Limits of Explanation

Perhaps the deepest question in ontology is when (if ever) it is legitimate to postulate the existence of entities (like possible worlds, facts, or properties) that are not evident in experience. Some philosophers insist that it never is. Others urge that at least some entities of this sort, in particular properties, have no explanatory power and that appeals to them are vacuous or otherwise illegitimate (e.g., Quine, 1961, p. 10; Quinton 1973, p. 295).

The more heavy-handed dismissals of properties and other metaphysical creatures have often been based on faulty accounts of concept formation (which led Hume to counsel consignment of metaphysical works to the flames) or defective theories of meaning (which led many positivists to view metaphysics as a series of pseudo explanations offered to solve pseudo problems). Wittgenstein takes a more subtle approach, trying to show us that 'our disease is one of wanting explanations' (1991, Pt VI, 31) and striving to cure us of it. Swoyer (1999) has attempted some defense of explanation by postulation in ontology, but the issues are difficult ones that are not amenable to proof or disproof. Fortunately the present task is not to defend explanation in ontology, but it will be useful to briefly note two general views about such explanations.

Two Views of Explanation in Ontology

Metaphysics has traditionally been viewed as first philosophy, and some philosophers hold that its arguments should be demonstrative. Recently Linsky & Zalta (1995) have argued that it is possible to give a transcendental argument for the existence of properties; if this argument is successful, it is demonstrative, and they claim that its conclusion (that a wide range of properties exist) is synthetic *a priori*. Others (e.g., Swoyer, 1983; 1999) urge that most of the arguments advanced on behalf of properties appear anemic when judged by the demonstrative ideal, but that they look much better when

viewed as inferences to the best explanations. We will not pursue this issue, however, since it is impossible to form a satisfactory view about the nature of philosophical explanations in a vacuum. An account of metaphysical explanation should instead emerge from a consideration of the more plausible metaphysical explanations, and we will focus on such explanations here.

2.2 Constraints on Explanations Employing Properties

Parochial Constraints

Philosophical explanations are usually thought to be constrained in various ways, but beyond philosophical family values like consistency, parsimony and comprehensiveness these constraints will often seem parochial to those philosophers who are not committed to them. In Medieval disputations about universals, for example, religion and theology were fundamental, and it was widely held that any account of properties should be able to explain the Trinity, the Eucharist, and the absolutely unchanging nature of God (this last requirement often led to quite tortured accounts of the relations holding between protean finite beings and God). But few philosophers in our naturalistic era would give such considerations a second thought.

More General Constraints

Some proposed constraints on metaphysical explanation depend on more general philosophical orientations. For example, Russell's Principle of Acquaintance, the injunction that we only admit items into our ontology if we are directly acquainted with them, expresses an strong empiricist sentiment. Other constraints are more directly metaphysical. For example, Aristotle upbraids Plato for separating the Forms from their instances, suggesting that this renders them incapable of explaining anything (e.g., *Metaphysics*,1079b11--1080a10). His point seems to be that properties could explain things about individuals only if they were located *in* those individuals. The sentiment is that an individual, spatio-temporal object (like my cat) which stands in some obscure relation to some entity entirely outside of space and time (say the Form of the cat) cannot explain anything about the cat itself.

Mandatory Constraints

All accounts of properties must avoid various perennial objections to them. Three criticisms of this sort were anticipated by Plato (worrying about his own doctrines) in the *Parmenides*.

First, it appears that a universal property can be in two completely different places (i.e., in two different instances) at the same time, but ordinary things can never be separated from themselves in this way. There are scattered individuals (like the former British Empire), but they have different spatial parts in different places. Properties, by contrast, do not seem to have spatial parts; indeed, they are sometimes said to be wholly-present in each of their instances. But how could a single thing be wholly present in widely separated locations?

This conundrum has worried some philosophers so much that they have opted for an ontology of tropes in order to avoid it, but realists have two lines of reply (both of which commit us to fairly definite views about the nature of properties). One response is that properties are not located in their instances (or anywhere else), so they are never located in two places at once. The other response is that this objection wrongly judges properties by standards that are only appropriate for individuals. Properties are a very different sort of entity, and they *can* exist in more than one place at the same time without needing spatial parts to do so.

Second, some properties seem to exemplify themselves. For example, if properties are abstract objects, then the property of being abstract should itself exemplify the property of being abstract. In various passages throughout his dialogues Plato appears to hold that Forms (which are often taken to be his version of properties) participate in themselves. Indeed, this claim serves as a premise in what is known as his *Third-Man Argument* which, he seems to think, may show that the very notion of a Form is incoherent (*Parmenides*, 132ff). Russell's paradox raises more serious worries about self-exemplification. It shows that any account which allows properties to exemplify themselves must be carefully formulated if it is to avoid paradox (a polite word for inconsistency).

Third, many critics have charged that properties generate vicious regresses, e.g., the one exhibited in Plato's third man argument or Bradley's regress, and any viable account of properties must have the resources to avoid them.

The disputes about plausible constraints on property-invoking explanations, together with the obvious difficulty of settling such disputes, leave the situation murkier than we would wish. We will see that the use of properties to explain phenomena in the philosophy of mathematics or naturalistic ontology or the semantics of natural languages imposes additional, tighter, constraints that make it easier to evaluate competing accounts. But constraints of the sort noted here have played a central role in many philosophical discussions of properties, and we will often fail to understand those discussions if we forget this.

2.3 The Fundamental Ontological Tradeoff

Metaphysics, like life, is full of tradeoffs, cost-benefit analyses, the attempt to simultaneously satisfy competing constraints. In ontology we must frequently weigh tradeoffs between various desiderata, e.g., between simplicity and comprehensiveness, and even between different kinds of simplicity. But one tradeoff is so pervasive that it deserves a name, and I will call it *the fundamental ontological tradeoff*. The fundamental ontological tradeoff reflects the perennial tension between explanatory power and epistemic risk, between a rich, lavish ontology that promises to explain a great deal and a more modest ontology that promises epistemological security. The more machinery we postulate, the more we might hope to explain--but the harder it is to believe in the existence of all the machinery.

The dialectic between a realism with chutzpah and a diffident empiricism runs all through philosophy, from ethics to philosophy of science to philosophy of mathematics to metaphysics. Excessive versions of

each view are usually unappealing. Extreme realists ask us to believe in things many philosophers find it difficult to believe in; extreme empiricists wind up unable to explain much of anything. But the dialectic between power and risk remains even when we move in from the extremes. It often manifests itself in a yearning for parsimony, a desire for as few entities as we can scrimp by with. Such longings may seem prudish or stuffy or a bit too metaphysically correct. Often the desire is not to achieve parsimony for its own sake, however, but to find an ontology that is modest enough to provide a measure of epistemological security. Choices needn't be all or none, and a principled middle ground is always worth striving for. But no matter where a philosopher tries to stake her claim, the fundamental ontological tradeoff can rarely be avoided and we will encounter it frequently in what follows.

3 Traditional Explanations: An Unscientific Survey

Properties have been invoked to explain a very wide range of phenomena. The things to be explained (*explananda*; singular *explanandum*) are a mixed bag, and the explanations vary greatly in plausibility. To fix ideas, we will note several of the most common explanations philosophers have asked properties to provide (for a longer list see Swoyer, 1999, §3).

Resemblance and Recurrence

There are objective similarities or groupings in the world. Some things are alike in certain ways. They have the same color or shape or size; they are protons or lemons or central processing units. A puzzle, sometimes called the problem of the *One over the Many*, asks for an account of this. Possession of a common property (e.g., a given shade of yellow) or a common constellation of properties (e.g., those essential to lemons) has often been cited to explain such resemblance. Similarly, different groups of things, e.g., Bill and Hillary, George and Barbara, can be related in similar ways, and the postulation of a relation (here *being married to*) that each pair jointly instantiates is often cited to explain this similarity. Finally, having different properties, e.g., different colors, is often said to explain qualitative differences. A desire to explain qualitative similarity and qualitative difference has been a traditional motivation for realism with respect to universals, and it continues to motivate many realists today (e.g., Armstrong, 1984, p 250; Butchvarov, 1966; Aaron, 1967, ch. 9).

Recognition of New and Novel Instances

Many organisms easily recognize and classify newly encountered objects as yellow or round or lemons or rocks, they can recognize that one new thing is larger than a second, and so on. Some philosophers have urged that this ability is based partly on the fact that the novel instances have a property that the organism has encountered before--the old and new cases share a common property--and that the creature is somehow attuned to recognize *it*.

Meaning

Our ability to use general terms (like ‘yellow, ‘lemon’, ‘heavier than’, ‘between’) provides a linguistic counterpart to the epistemological phenomenon of recognition and to the metaphysical problem of the One over the Many. Most general terms apply to some things but not to others, and in many cases competent speakers have little trouble knowing when they apply and when they do not. Philosophers have often argued that possession of a common property (like *redness*), together with certain linguistic conventions, explains why general terms apply to the things that they do. For example Plato noted that ‘we are in the habit of postulating one unique Form for each plurality of objects to which we apply a common name’ (*Republic*, 596A; see also *Phaedo* 78e, *Timaeus*, 52a, *Parmenides*, 13; Russell, *Problems of Philosophy*, p. 93). Questions about the meanings (now often known as the ‘semantic values’) of singular terms like ‘honesty’ and ‘hunger’ and ‘being in love’ may be even more pressing, since the chief task of such terms seems to be to *refer* to things. But what could a word like ‘honesty’ refer to? If there are properties, it could refer to the property *honesty*.

Unification and Triangulation

In a brilliant paper on Plato's theory of Forms (which, as noted above, are often taken to be his version of properties), the classicist H. F. Cherniss (1936) argues that Plato intended his theory to solve three fundamental philosophical problems. By the end of the fifth century B.C. the arguments and conundrums of philosophers had cast doubt on several things that Plato thought were obviously true. In ethics Protagorean relativism threatened the view that ethical principles could be objective; in the clamor of individual disagreements, clashes between cultures, and the failure of philosophical inquiry to locate any firm ground, the challenge was to *explain* how ethical objectivity was possible. When Plato turned to epistemology, various considerations convinced him that there was an important difference between knowledge (*episteme*) and belief (*doxa*), even between knowledge and *true* belief (right opinion). But how could we explain that? Finally, in metaphysics it seemed clear that things change in various ways, but the arguments of Parmenides made even this seem mysterious.

Plato drew on his Forms to explain how these three phenomena were possible. On his view, the Forms exist pure and unadulterated by human thought, and some Forms, most prominently the Good, offer objective standards for values like goodness and justice. In epistemology Plato attempted to explain the difference between knowledge and belief by arguing that Forms are the objects of the former but not the latter (e.g., *Timaeus*, 51d3ff). In metaphysics Plato argued that change is only possible against a background of things that do not change, and he urged that the Forms provided this (*Cratylus*, 439d3ff). Finally, although Cherniss doesn't mention it, Plato's theory of Forms helped explain the semantics of general terms (as suggested in *Republic*, 596A).

This isn't to say that all, or indeed any, of Plato's explanations were successful. But it is worth noting that many philosophers still invoke properties to account for the sorts of things Plato struggled to explain. Early in this century G. E. Moore offered an alternative to ethical naturalism by claiming that goodness is a simple, non-natural property. Few contemporary philosophers would accept Moore's anti-naturalism or his account of non-natural properties, but many would defend ethical naturalism by arguing that moral properties supervene on naturalistically respectable properties.

Virtually no philosophers accept Plato's account of the difference between knowledge and belief, but many still hold that properties have an important role to play in explaining epistemological phenomena. For example, Russell (1912, ch. 10) argued that the only way to explain the possibility of *a priori* knowledge is to regard it as knowledge of relations among universals . Most philosophers today would question this, but many of them would agree that properties have an important role to play in explaining such epistemological phenomena as our ability to recognize and categorize things in the world around us.

Few contemporary philosophers would endorse Plato's claims about the need for some permanent backdrop for flux, but properties can still be cited to explain change. If my pet chameleon was brown all over yesterday and is green all over today, then the brute existence of the creature isn't enough to explain the change; after all, *he* persisted throughout. But, some philosophers urge, we can explain the alteration by noting that the chameleon exemplified the property *brownness* yesterday but he exemplifies the property *greenness* today.

Finally, many philosophers would concur that Plato's account of the meanings of general terms was on the right track, though as we shall see in §4.2, current accounts of meaning have moved far beyond Plato's in their detail and formal sophistication.

Explanation by Unification

This brief survey of putative explanations that rely on properties isn't meant to be detailed or exhaustive; the point is simply to illustrate how a range of accounts employ properties in an effort to explain philosophically puzzling phenomena. Just as importantly, Plato's account suggests an attractive model for philosophical explanation. A general pattern of explanation by *unification*, *integration* or *systematization* is at work in his attempt to solve three, superficially disparate, problems using the same resources. He attempts to show that at a fundamental level the three phenomena are related, linked by the Forms and the principles than govern them. This unification has explanatory value, since it allows us to see a single pattern or entity at work in a range of superficially diverse cases. At all events, this is one explanatory virtue in the natural sciences, clearly at work in the work of Newton and Maxwell and Darwin, and it is also a pattern we find in Plato's account.

An account that employs properties to do multiple tasks has two further virtues. First, insofar as each of the explanations is plausible, it serves as part of a *cumulative case* for the existence of properties. Second, if properties can perform multiple tasks, they must simultaneously satisfy multiple constraints, and so different sorts of data can be used to test a theory of properties. The hope is that by considering several tasks of this sort we could begin to triangulate in on the nature of properties; we could begin to see what features properties would need to have in order to play each of the different explanatory roles. It may turn out, of course, that entities well-suited to one explanatory role will be ill-suited to another. For example, we will see below that the existence and identity conditions of entities used to account for causation may be rather different from those needed by entities that could serve as the meanings of intentional idioms (like ‘is thinking of Vienna’). This might lead us to postulate the existence of several kinds of properties; alternatively, it might lead us to conclude that properties cannot do all of the things philosophers has hoped that they could. Either way, as fragmentation increases, cumulative support and triangulation on

the nature of properties will slip away.

4 What have you done for us lately? Recent Explanations

Properties alone cannot explain much of anything. A *theory* of properties--an account that tells us what properties are *like* and *how* they do what they are invoked to do--is required for that. A number of theories of properties have been developed over the last quarter century, and many of them possess much more depth, sophistication, and formal detail than the no-frills accounts alluded to in the previous section. I will focus on explanations in three areas where properties are often invoked today: philosophy of mathematics, semantics (the theory of meaning), and naturalistic ontology. These areas are also useful to consider, because if properties can explain things of interest to philosophers who don't specialize in metaphysics, things like mathematical truth or the nature of natural laws, then properties will seem more interesting. Unlike the substantial forms derided by early modern philosophers as dormitive virtues, properties will pay their way by doing interesting and important work.

My aim is to indicate the general lay of the land and point the way to more detailed discussions that interested readers can follow up. In each of the three cases I will indicate:

1. **What is to be explained**. As with most things in philosophy, there is often some controversy over which things in a given area stand in need of philosophical explanation. In some cases a few philosophers question the very existence of the things that other philosophers think require explanation; for example, able philosophers have denied that there are such things as mathematical truth (e.g., Field, 1980) or laws of nature (e.g., van Fraassen, 1989). And even those philosophers who think that we need to explain certain things, e.g., various features of mathematical truth, may disagree about precisely what those features are. In the three areas examined in this section, however, there is a reasonable degree of consensus about which things stand in need of explanation, and I will focus on these.
2. **How properties explain**. In some cases different philosophers use properties in different ways to explain the same phenomenon. I will focus on the simpler, more common approaches. We will also see that in most cases a theory of properties only explains things when it is conjoined with various background assumptions or auxiliary hypotheses.
3. **Beating the competition**. Arguments that properties exist because they explain some particular phenomenon (like qualitative recurrence or mathematical truth) are weak if other sorts of entities can account for it just as well. Arguments that alternative accounts don't work, especially when they involve alternative putative entities (like sets or tropes), are typically based on the claim that these entities lack the requisite features to account for the explanandum. I will also note a few cases where proponents of one account of properties argue against proponents of a rival account, since these arguments typically involve disputes over the nature of properties.
4. **Difficulties**. Almost all explanations that employ properties face difficulties, and I will briefly indicate the most serious of these.

5. **Lessons the explanations teach us about properties**. Properties often must have certain features in order to provide certain explanations. So once we have examined a given explanation, we will ask what properties would have to be *like* in order to provide it. In particular, we will ask what lessons are to be learned about the existence and identity conditions of properties, their structure (if any), and their modal and epistemic status.

4.1 Mathematics

Philosophers of mathematics have focused much (arguably too much) of their attention on number theory (arithmetic). Number theory is just the theory of the natural numbers, 0, 1, 2, ..., and the familiar operations (like addition and multiplication) on them. Many sentences of arithmetic, e.g., ‘7 + 5 = 12’ certainly seem to be true, but such truths present various philosophical puzzles and philosophers have tried to explain how they *could* have the features they seem to have.

Explananda in Philosophy of Mathematics

Most wish lists include hopes for explanations of at least five (putative) facts; philosophers want to know:

1. How the sentences of arithmetic can have truth values (how they can be true or false)
2. How the sentences of arithmetic can be objectively true (or false), independently of human language and thought
3. What the logical forms of the sentences of arithmetic are
4. How the sentences of arithmetic can be necessarily true (or necessarily false)
5. How the truth values of sentences of arithmetic can be known independently of experience (*a priori*), save for a modicum of experience needed to acquire mathematical concepts

Sample Explanations

Identificationism

Most attempts to use properties to explain the items on this list are versions of *identificationism*, the reductionist strategy that *identifies* numbers with things that initially seem to be different. This approach is familiar from the original versions of identificationism where numbers were identified with sets, but it is straightforward to adapt this earlier work to identify numbers with properties rather than with sets.

Properties vs. Sets

Sets are often contrasted with properties, and before proceeding it is important to note a fundamental difference between the two. If *x* and *y* are sets and have exactly the same members, then *x* and *y* are one and the same set. When *x* and *y* have precisely the same members they are said to have the same *extension*, and sets are often called *extensional* entities. Just as sets can have members, properties can have instances, things that exemplify or instantiate them, and this relation of exemplification is to

properties what the membership relation is to sets.

The identity conditions of properties are a matter of dispute. Everyone who believes there are properties at all, however, agrees that numerically distinct properties *can* have exactly the same instances without being identical. Even if it turns out that exactly the same things exemplify a given shade of green and circularity, these two properties are still distinct. For this reason properties are often said to be *intensional* entities, although people often concur with this because they agree about what properties' identity conditions are *not* (they aren't extensional), rather than because they agree about what their identity conditions *are*.

The ABCs of identificationism

If we have a rich enough theory of properties, it is possible to retrace the steps of earlier versions of identificationism using properties in place of sets. The property theorist can formulate axioms for property theory that parallel the axioms of standard set theories (save for replacing the axiom of extensionality with some other identity condition, perhaps omitting the axiom of foundations, and making other minor emendations to adapt the ideas better to properties; e.g., Jubien, 1989; cf. Bealer, 1982, Ch. 6; Pollard and Martin, 1986).

There are infinitely many natural numbers (the collection of natural numbers in fact has the smallest size an infinite collection can have), so the first step in identificationist programs is to find (or postulate, or imagine) an infinite realm of properties. The next step is to identify one denizen of this realm with the number zero and to identify some operation on this realm of entities with the successor function. The key here is that successive iterations of the function yield a new and different entity every time it's applied.

There are two major species of identificationism. The first views the reducing theory (of sets, or of properties) as a branch of logic; the second views it as a substantive theory (of sets, or of properties) that makes commitments over and above those made by logic. There are important differences between the two approaches, but given the very strong nature of the logic required for logicist identificationism, the differences do not matter greatly here so I will treat both approaches together. (For a discussion of the differences, see Section 1 ("Logicist Identificationism") of the supplementary document Uses of Properties in the Philosophy of Mathematics.)

Identificationist accounts treat ‘1’ and ‘2’ as singular terms that refer to properties (those properties that are identified as the numbers 1 and 2), and they treat predicates and function symbols as denoting relations and functions. Thus, since the semantics values of ‘1’ and ‘2’ are in the extension of the relation expressed by the predicate ‘<’, the sentence ‘1 < 2’ is true and, indeed, it has the simple logical form of a predication of a two-place predicate, ‘<’, with two singular terms, ‘1’ and ‘2’, i.e., it has the simple logical form *Rxy*. We apply this idea to all atomic sentences in the language of arithmetic and then extend the account to all sentences in this language by the usual recursive treatments of the logical constants.

This explains how sentences of arithmetic can be objectively true (wishes 1 and 2): they are true because

they describe an objective realm of mind-independent properties. And since the language we use has a straightforward referential semantics, it also supplies a very natural and straightforward account of the logical forms of the sentences of number theory (wish 3). Finally, if the properties identified with numbers are ones that exist necessarily, and if they necessarily stand in the arithmetical relations that they do, the truths of arithmetic will be necessarily true (wish 4). But taken alone property-based identificationism does not explain mathematical knowledge (wish 5; we will return to this matter below).

Some recent accounts identify numbers with properties that seem less other-worldly than those invoked by mainstream identificationists. For example, Bigelow and Pargetter (1990) argue that rational numbers are higher-order relations--*ratios*--among certain kinds of first-order relations. The leading idea is that if Bill is twice as tall as Sam, then Bill stands in the relation *twice as tall* to Sam. This relation in turn stands in the (second-order) ratio relation of 2:1 to the identity relation among objects. Such higher-order ratio relations are isomorphic to the rational numbers, and Bigelow and Pargetter go on to *identify* them with the rational numbers. Thus, the second-order relation 5:1 turns out to be the number five. It isn't clear how to extend the ideas to large infinite cardinals or to ordinal numbers, but they propose extending the idea to second-order relations of proportion, and identifying the reals with such proportions.

Other Property-based accounts in the Philosophy of Mathematics

There are also several non-identificationist accounts of mathematical truth that make use of properties.

Structuralism

The most important features, perhaps the only features, of the natural numbers are structural ones. These are the features that axiomatizations capture (zero is the first member of a countably infinite sequence, each member of the sequence has exactly one member that follows it, etc.). Such sequences are said to be omega-sequences. Structuralists (often inspired by Benacerraf, 1965) take this idea to heart and argue that any omega-sequence can play the role of the natural numbers (cf. Resnik, 1995). They claim that it's the *structure* that such sequences have in common, rather than the particular entities that happen to populate them, that are important for mathematics. And one way to develop this idea is to think of an omega-sequence as a very complex, relational property that could be instantiated by actual sequences of objects of the appropriate sort.

Structuralist accounts avoid one of the problems noted below (that of isomorphic models) which besets all versions of identificationism. They may also make the epistemology of mathematics slightly less puzzling, since many structural or pattern-like properties can be instantiated in the things we perceive (we perceive such a property when we recognize a melody played in different keys, for example). But they cannot deliver explanations of the truth conditions and logical forms of arithmetical sentences that are as straightforward as those provided by identificationist accounts since they don't offer us any objects to serve as the referents of the numerals.

Abstract individuals and situations

Linsky and Zalta (1995) develop a novel account of mathematical truth using Zalta's (1983) theory of abstract objects. (The account is developed in much more detail in Zalta (2000) and (1999).) It is relevant here because it is developed along side a formal account of properties that rivals Bealer's in scope and detail. Abstract objects are correlated with collections of properties (which needn't be either maximal or consistent), situations are defined as a special sort of abstract object, and mathematical theories are identified with situations that encode only propositional properties. The account is too detailed to present here, but we will discuss Zalta's basic ideas below when we turn to the identity conditions of properties.

Beating the Competition

The most obvious competitors to property-based accounts of mathematical truth identify numbers with sets, and as long as we focus *solely* on mathematics, sets may seem more appealing. After all, sets do have clearer identity conditions than properties. Moreover, the iterative conception of sets, a picture according to which they form a natural hierarchy, fits nicely with our picture of the structure of natural numbers, whereas an iterative conception of properties is less natural. Finally, set theory provides a powerful unifying framework in which all sorts of mathematical entities, like functions and spaces, can be reconstructed (or at least represented) in a common idiom and dealt with by a common stock of techniques (like proofs by mathematical induction).

The most compelling defense of the use of properties in the philosophy of mathematics urges that when we step back and consider the big picture we see that a rich enough stock of properties can do all the work of sets (and numbers--or that we can use them to define sets or numbers) *and* that properties can do further things that sets simply cannot. For example, it has been argued that properties can be used to give accounts of the semantics of English or explain the nature of natural laws. The appeal of sets, in short, results from a metaphysical myopia, but once we adopt a larger view of things we find that properties provide the best global, overall explanation.

Difficulties

The gravest threats to identificationism are posed by what might be called the *Benacerraf problems*. Authors who defend such accounts are aware of these difficulties and have proposed various responses to them, but the problems are serious and no solutions are generally accepted.

The Problem of Isomorphic Identifications

As Benacerraf (1965) noted, if there is one way to identify the natural numbers with sets, there are countless ways, e.g., Frege's, Zermelo's, von Neumann's, etc. (For a brief discussion of this, see Section 2 ("Set-theoretic Identificationism") of the supplementary document Uses of Properties in the Philosophy of Mathematics.) Some accounts are better for certain purposes than others. But no account is best for all purposes, and if one was, no one has ever explained how it would follow that *it* was the true story about numbers.

There is a similar arbitrariness in any particular identification of numbers with properties (as the fact that different property theorists identify numbers with different properties shows). The point is most obvious with those theories that treat properties as intensional analogues of sets, since it is well-known that numbers can be identified with sets in myriad ways. But it will be a problem for any identificatory program, since there will be many isomorphic models of number theory in the realm of properties (if it is commodious enough to provide any models at all). And there is no reason for thinking that any particular model gives The One True Story about what the numbers actually are.

This difficulty also threatens less formal property-based accounts. For example, there is some arbitrariness in Bigelow and Pargetter's identifications, since we can find many different models of the theory of rational numbers among the realm of ratio relations (e.g., we could identify *n/m* with the relation *n:m* or with the relation *m:n*), and there is no clear reason to suppose that one identification is the right one.

The Problem of Epistemic Access

The second problem, suggested by Benacerraf (1973) a few years later, is that most versions of identificationism propose to identify numbers with putative objects that lie outside the spatio-temporal, causal order. The problem is that we are physical organisms living in a spatio-temporal world who cannot interact causally (or in any other discernible way) with abstract, causally inert things. Few people are aware of having any special cognitive faculty that puts them in touch with a timeless realm of abstract objects, neuroscientists have never found any system in the brain that subserves such a capacity, such a story is not suggested by what is known about the ways in which children acquire numerical concepts, and nothing in physics remotely suggests any way in which a physical system (the brain) can make any sort of contact with causally inert, non-physical objects. None of this proves that we don't have some sort of access to an abstract realm of objects, but the claim that we do leaves the epistemology of mathematics a mystery and, more importantly, there seems to be little positive reason to suppose that it's true.

A few philosophers, e.g., Linsky & Zalta (1995) have taken the problem of epistemic access seriously, and proposed solutions that do not involve mysterious cognitive faculties. Philosophers remain divided on this issue, but it is safe to say that if the problem of epistemic access cannot be overcome, it in turn undermines identificationist attempts to use properties to explain arithmetic truth. If we cannot gain epistemic access to the realm of numbers, then there is no clear way for us to establish connections between the items of our language (e.g., ‘one’) and the numbers they denote. We can't, for example, say that zero is the first number until we manage to attach the word ‘number’ to the realm of numbers. It might seem that we could avoid this difficulty by using purely structural descriptions, ones employing only logical vocabulary, for the task. If such descriptions were couched in a sufficiently powerful language they could be used to characterize the natural numbers up to isomorphism. Such a characterization is all we could ask of any formalization, but it isn't enough to pick out the natural numbers themselves, since if there is one model of a purely structural sentence incorporating such a description, there will be many. For example, such a sentence will have models in the domains of the positive real numbers, the negative real numbers, many fragments of the iterative hierarchy of sets, and so on.

Once again we face the fundamental ontological tradeoff: A richer ontology offers to explain many things that might otherwise be mysterious. But in the view of many philosophers, it engenders epistemological mysteries of its own.

Excursus: Other Reductions

Identificationists sometimes speak of *reducing* numbers to properties. Similarly, one might hope to reduce other things, e.g., possible worlds, to properties (e.g., Zalta, 1983, §4.2; Forrest, 1986). The aim is to show that they such things are nothing over and above very complicated properties.

Bundle Theories

One of the most interesting reductionist programs attempts to reduce individuals or particulars to collections of properties. Such programs are often called *bundle theories*, since they identify ordinary individuals with bundles of properties. Russell (1948, Pt. IV, ch. 8) developed one account of this sort in which individuals were treated as properties linked together by a relation he called *compresence*. The evaluation of such accounts would require an excursus into the ontology of individuals where issues like the problem of individuation, the identity of indiscernibles, and identity through time loom large. Such matters lie outside the scope of our present discussion, though it is worth noting that they involve a purer version of ontology than theories of properties; they have relatively few implications outside of ontology itself.

Lessons About Properties

What do property-based versions of identificationism tell us about the *nature* of properties? We can read off minimum requirements from the fact that in this domain sets can do most of the work that properties are invoked to do.

> **Existence Conditions:** We require an infinite realm containing at least aleph-null (the smallest infinite cardinal number) many properties. Depending on our aspirations, we may need many more. For example, if we want to work with huge transfinite cardinal numbers, we will need a very large infinity of properties.
>
> **Identity Conditions:** Formalized mathematics is one of the few domains where extensionality reigns, and the fact that sets can be used as surrogates of the natural numbers tells us that entities with very coarse-grained identity conditions can do at least most of the work of numbers.
>
> **Structure:** The realm of properties has to include enough relations among properties to give it the structure of an omega-sequence. And if we want to identify others sorts of numbers, e.g., the real, or complex, or transfinite ordinal numbers, with properties, we will

require many additional properties as well as further relations to structure them in the right sorts of ways.

Modal Status: If the truths or arithmetic are necessarily true, then we need a realm of necessarily existing properties that necessarily stand in the (mathematically relevant) relations that they do.

Epistemic Status: If the truths of arithmetic can be known *a priori*, then the arithmetic features of those properties that play the role of numbers must be knowable *a priori*.

4.2 Semantics and Logical Form

Language and logic have long been an important source of data for ontologists. Many philosophers have contented themselves with fairly informal appeals to various features of language to support their claim that properties exist, but in the last two decades some philosophers (along with a few linguists and even computer scientists) have employed properties as parts of detailed accounts of the semantics (meaning) of large fragments of natural languages like English or Choctaw, and some of these accounts contain the most detailed formal theories of properties ever devised. Some property theorists are motivated almost exclusively by a desire to give a semantic account of natural language (e.g., Chierchia and Turner, 1988), others hold that this is but one of several motivations for developing an account of properties (e.g., Bealer, 1982; Zalta, 1993), but it should be noted that still others (e.g., Jubien, 1989; Armstrong, 1997; cf. Mellor, 1986, pp. 180ff) doubt that properties have any serious role to play in semantics at all.

Explananda in Semantics

Logical form

Semantic accounts often go hand in hand with theories of logical form. *Logical form* is a technical notion motivated by the observation that sentences with a similar surface structure may exhibit quite different logical behavior. For example, ‘John is tall and Tom is tall’ entails ‘Tom is tall’, but ‘You show me someone who dislikes John and I'll show you a real misanthrope’ does not entail ‘I'll show you a real misanthrope’. Furthermore, sentences that appear different on the surface may exhibit similar logical behavior. For example, ‘You show me someone who dislikes John and I'll show you a real misanthrope’ and ‘If you show me someone who dislikes John, then I'll show you a real misanthrope’ evince similar logical behavior.

Such facts led various philosophers to introduce a theoretical notion of logical form and to use it to provide theoretical redescriptions of sentences in terms of their logical form in a way that allows us to explain their logical features (e.g., why they are consistent with some sentences but not with others or why they entail the sentences they do). Although philosophers differ in how systematic they are in developing such accounts, most arguments to the effect that properties are needed to explain linguistic phenomena are linked to some conception of logical form.

Sample Explanations

Informal appeals to language and logic

We will begin with four linguistic phenomena that might be explained by a relatively informal and somewhat piecemeal account of properties.

1. General terms like ‘blue’ and ‘honest’ can apply to a variety of things, they apply to the things that they do partly because of their meanings, and in some cases where two predicates in fact apply to exactly the same things, they could have applied to different things.
2. Abstract singular terms like ‘courage’ can occupy subject position in true sentences (‘Courage is a virtue’), they seem to be referring singular terms, and many of sentences of this sort (e.g., ‘Courage is Tom's favorite virtue’) cannot be paraphrased in a way that eliminates the abstract singular term.
3. We can use pronouns (which certainly seem to be referring expressions) that are anaphorically linked back to predicates (‘Clinton is undisciplined, and *that* is a bad quality in a president’) or to terms in subject position like gerunds (‘Being undisciplined is deplorable, and *it* also endangers others’).
4. Many sentences of English appear to quantify over the semantics values of predicates (‘Clinton is tenacious, so there is at least one virtue that he has’) or abstract singular terms (‘Lethargy is a symptom of mononucleosis, so there is at least one symptom of that malady’). And although some of these sentences can perhaps be paraphrased or reconstrued in ways that dispel the appearance of quantification, many have resisted years of such attempts. For example, ‘There are some properties that will never be named’ cannot be interpreted as an ontologically harmless substitutional quantification. We can also count the things predicates or abstract singular terms stand for (e.g., ‘There are exactly two symptoms that mononucleosis and Barr-Epstein syndrome have in common’) and abstract singular terms can flank the identity predicate (e.g., ‘I believe in the unity of virtue: courage and temperance are the same thing’).

As long as we lack a precise mathematical characterization of English, it isn't possible to *prove* that certain idioms cannot be paraphrased away. But the use of abstract singular terms is so common and the failures of attempts to paraphrase them away are so clearcut that there is no reason to think that they could be eliminated from English without eviscerating it.

A relatively unsophisticated account of properties can be mobilized to explain the four phenomena listed above in a way that allows us to use a relatively straightforward referential semantics with objectual quantifiers. Such accounts explain the meanings of general terms (item 1) like ‘honest’ by claiming that they denote (or express) properties (like *honesty*), that a sentence like ‘Tom is honest’ has the logical form of a simple, subject-predicate sentence, and that it is true just in case the individual denoted by ‘Tom’ is in the extension of the property denoted (or expressed) by the predicate ‘honest’, which requires that there be a property expressed by this predicate (a slightly more formal account is given below; see Hochberg, 1968, for a good discussion of related issues).

In a similar spirit, some philosophers argue that abstract singular terms like ‘honesty’ (item 2) *denote* the property that the associated predicate (‘honest’) denotes or expresses, that sentences like ‘Honesty is a virtue’ have the simple logical form of a subject-predicate sentence, and that the sentence is true exactly when the word ‘honesty’ denotes a property that is in the extension of the property denoted by the verb phrase ‘is a virtue’.

Once we take these steps, it is also straightforward to explain the remaining items on our list. For example the validity of the argument: ‘Clinton is self-indulgent; therefore, there is at least one vice that Clinton has’ can be explained as follows: The logical form of the premise is that a simple subject-predicate sentence and the logical from of the conclusion is that of an existential quantification with a standard objectual quantifier. If the first sentence is true, then ‘self-indulgent’ expresses a property, and this property satisfies the open sentence ‘Clinton is X’. Hence, just as in standard first-order logic, the existential quantification is true. Similar maneuvers allows us to explain the remaining items on this list: if properties are genuine things, then we can count them and we can use different expressions to stand for the same property.

These explanations rely on little more than the following three claims. First, there is a rich enough stock of properties to provide a semantic value (meaning) for every predicate and abstract singular term of English (or better, for all of those that could have such semantic values without leading to paradox). Second, sentences like ‘Courage is a virtue’ and ‘John is courageous’ are simple subject-predicate sentences. Third, such sentences are true just in case the thing denoted by the subject is in the extension of the property denoted (or expressed) by the predicate.

These simple assumptions account for the phenomena on our list in a much better way than their more prominent rivals can. Some philosophers, for example, hold that predicates have a multiple denotation (multiply denoting all of the things to which they apply). Others hold that the semantic values of predicates are sets (the sets of things to which they apply). But these accounts cannot explain the fact that many pairs of predicates that in fact have the same extension (and hence the same multiple denotation‘) *could* have applied to different groups of things and that their meanings are precisely what allow them to do so. Even more seriously, these two rivals have no plausible account at all of the last three items on the list.

More formal accounts of language and logic

If the goal is simply to argue that there are properties because there is no other way to explain several obvious linguistic and logical phenomena (which is all many philosophers have aspired to show), then the simple accounts sketched above make a plausible (though certainly not unassailable) start. Some philosophers have set their sights higher, however, wanting to provide a rigorous and systematic account of the semantics of a large fragment of English. They try to work the above ideas out in a more detailed way and to extend them to deal with more complex phenomena, including the following:

1. Various English constructions are quite naturally interpreted as complex predicates: ‘Tom is a

boring but honest brother of Sam' is straightforwardly construed as a containing a compound predicate, 'is a boring but honest brother of Sam' that is predicated of the noun 'Tom' (and that could be predicated of other nouns too, e.g., 'Wilbur'). Other constructions are very naturally interpreted as complex singular terms (as in 'Being a boring but honest brother of Sam is no bed of roses'). Furthermore, these complex expressions are related to simpler expressions in systematic ways. For example, 'Tom is a boring but not dishonest brother of Sam' should entail 'Tom is not dishonest'.

2. English is full of intensional idioms like 'necessarily', 'believes' and 'imagines' that cannot be handled by any extensional semantics.

The simple, informal claim that there are properties cannot explain such phenomena in a systematic way, especially when they are combined (as in 'Tom believes that it is necessarily the case that being a seventh son is more like being a sixth son than like being a fifth son').

In recent years a number of philosophers (e.g., Bealer, 1982, 1994; Zalta, 1983, 1988; Chierchia & Turner, 1988; Menzel, 1993) have developed intricate accounts that include formal logics whose semantics provide systematic ways of forming "compound" properties (e.g., *loving Darla*) to serve as semantic values of complex predicates ('loves Darla') or complex singular terms ('loving Darla). The details of such accounts are too complex to pursue here (although a generic account of some of the central ideas will be sketched in §8). It should be noted, however, that most philosophers who aspire to a semantic account of large intensional fragments of English introduce propositions, which they treat as zero-place properties.

The proper treatment of intentional idioms like 'believes that' also require properties that are very finely individuated, probably as finely individuated as the linguistic expressions that denote or express them. For example Tom's grasp of logic may be so tenuous that he believes of Ortcutt that he is a spy and an auditor for the IRS but doubts that he is an auditor for the IRS and a spy. This is sometimes taken to suggest that *being a spy and an auditor for the IRS* is distinct from the (necessarily coextensive) property *being an auditor for the IRS and a spy*. To be sure, few people are guilty of such blatant lapses, but we can certainly make mistakes when necessarily coextensive properties are described in more complicated ways (such errors are routine in mathematics and logic).

On the plausible (though not inevitable) assumption that the structure of many of our thoughts is similar to the structure of the sentences we use to describe the contents of those thoughts ('Sam thinks Tom is boring but not dishonest'), we might also hope to use properties in an account of mental content that would in many ways parallel an account of the semantics of the more intensional fragments of English.

Beating the Competition

Accounts that treat the semantic values of predicates as sets can handle a certain amount of English if we are willing to twist ("regiment") it into a rather complex, even tortured logical form. But little is gained by this, since such approaches cannot accommodate such simple intensional phenomena as the fact that

two predicates might just happen to apply to exactly the same things even though they could have applied to different things. And extensional accounts do even worse with complex nominalizations or more complicated intensional idioms like ‘believes that’. Sets (of ordinary things) are simply too coarse-grained to make the fine distinctions semantic theories require.

Intensions

The only serious alternative to the use of properties in formal semantics treats the semantic values of noun phrases and verb phrases as *intensions*. Intensions are functions that assign a set to the expression at each possible world (or related set-theoretic devices that encode the same information). On such accounts, for example, the semantic value of ‘red’ is the function that maps each possible world to the set of things in that world that are red. Montague (1974) and linguists and philosophers inspired by his work have devised systems inspired by this idea that have great elegance and power. Nevertheless, properties are more natural and better suited to handle many linguistic constructions than intensions are.

Properties are more natural, because we learn the meanings of many predicates by ostension, and we group objects together when they share properties that seem salient or important. I recognize the sound of an oboe or the taste of rhubarb; these are very direct and simple experiences that seem completely unrelated to functions from huge infinite sets of possible worlds to objects therein. If we learn to recognize certain properties and categorize objects in terms of such properties, this is relatively easy to understand. But if the semantic values of predicates are intensions, meanings are now incredibly complicated set-theoretic objects that require a huge ontology of possible worlds and, often, merely possible individuals.

Properties are more useful in semantics than intensions because intensions are still too coarse-grained to explain many semantic phenomena involving intensional idioms. For example, semantic accounts that employ intensions would most naturally treat ‘lasted a fortnight’ and ‘lasted two weeks’ as having the same meaning (since they have the same intension), which makes it difficult for such accounts to explain how ‘Tom believes the battle lasted two weeks, but does not believe that it lasted a fortnight’ could be true. Various stratagems are available to deal with problematic cases like this, but they are much less natural and involve a much more dubious ontology (all those sets and possible worlds) than accounts that employ properties. Furthermore, intensions are unlikely to be able to perform tasks in areas outside semantics (like naturalistic ontology) that properties may be able to do. It is natural, for example, to suppose that things have the capacities that they do (e.g., the capacity to exert a force on a distant object) because of the properties they possess (e.g., gravitational mass). But it seems most unlikely that huge, set-theoretic intensions would be able to explain things like this.

Reductions of Properties

Some philosophers have construed intensions as providing a *reduction* of properties to intensions (properties are nothing over and above functions from the class of possible worlds to classes of objects). We have seen that this account has little to recommend it, and it is much better to view properties (including relations, and perhaps propositions) as primitive entities. Other philosophers, less concerned

with formal matters, have sometimes envisioned a reduction of properties to sets of tropes; a discussion of some of the issues this involves will be found in the entry on tropes.

Difficulties

Every large-scale theory of the semantics of English generates anomalies of one sort of another. Furthermore, some accounts require very large ontologies and very finely-drawn distinctions. For example, on really fine-grained accounts of the identity conditions of properties, the relations *loving* and the converse of its converse are distinct relations. Similarly, the properties *being red and square* and *being square and red* are distinct. We might wonder whether such distinctions exist and (if they do) what enables us to match the right linguistic expressions with the right relation? How *do* we match ‘red and square’ and ‘square and red’ with the correct members of the relevant pair of properties (we will return to this matter below)?

If the properties needed for semantics are completely isolated from the natural world, the epistemological problems noted in the previous subsection (on the philosophy of mathematics) resurface. We might hope to avoid this by holding that all properties are either instantiated or that they can be constructed by a series of applications of logical operations (like conjunction and negation) from properties that are instantiated. But it is far from clear that we can "construct" properties to serve as the semantic values for all English predicative expressions in this way. But could we define properties to serve as semantic values for all the predicates that lack instances? Expressions like ‘witch’ have a good bit of open texture, and it is at best an open question whether we can define them in terms of properties that are actually instantiated.

Current property-based semantic theories do not accommodate vagueness. This is a serious shortcoming, because vague predicates (like ‘bald’) and vague nominalizations (like ‘baldness’) are the rule, rather than the exception. When property-based semantic theories are modified to accommodate them, their proponents will have to decide whether vagueness is an objective feature in the world itself (so that some properties themselves are vague, in the sense of having vague or fuzzy extensions), or whether all vagueness resides in language (with properties having precise extensions and vagueness arising because it is sometimes somewhat indeterminate which sharp-edged property a given predicate or nominalization denotes).

Recent empirical work on concepts reinforces the point that many concepts (and, with them, predicates) have a graded membership and goes on to stress the importance of phenomena like typicality. Some creatures are more typical examples of birds than others, and there is some evidence that we determine whether something is a bird by assessing how similar (according to some psychological standard of similarity) it is to typical birds. This and various other phenomena have inspired a range of accounts of the structures of concepts, beginning with Rosch's (1978) account of prototypes and now including other accounts like exemplar theory (where we store exemplars of a concept in memory and determine what other things fall under that concept by assessing how similar they are to those exemplars).

Different accounts may well apply to different sorts of concepts (and perhaps, derivatively, to the predicates associated with them). For example, most mathematical concepts do have sharp boundaries, whereas many everyday concepts do not. On many recent psychological accounts, concepts involve features and similarity relations. Since features (e.g., having feathers, having a beak) are properties, there is no reason why current property theories could not be emended and extended to make contact with such accounts, and it seems likely that this will be a fruitful line of inquiry in the future (see Margolis & Laurence, 1999, for a useful selection of papers on concepts).

Lessons about Properties

What do semantic theories based on properties tell us about the *nature* of properties? The lessons here are less straightforward than in the philosophy of mathematics, partly because a detailed semantic theory must include a number of elements in addition to a theory of properties. For example, it must include a theory about the underlying logic in which the theory of properties is formulated, a theory about the logical forms of various English constructions (e.g., belief-sentences, gerundive phrases, parenthetical clauses), and perhaps claims that certain apparent entailment relations among English sentences don't really hold (e.g., because they are implicatures rather than logical entailments).

In short, we test a *total package* of such assumptions when we see how well a semantic theory accommodates our intuitions about what entails what or which groups of sentences are consistent. Moreover, somewhat different theories of properties may provide equally good accounts if we make compensatory adjustments in their underlying logics, in their accounts of the logical form of various constructions, or in our views about implicatures. Still, we have seen enough to draw some tentative lessons about properties from their use in semantics.

> **Existence Conditions:** If we want to account for the meanings of all predicates or all abstract singular terms (save for those which would lead to paradox), we need a very large stock of properties to serve as their semantic values (and since languages are extensible, we need properties to serve as the semantic values for any words that might ever be added).
>
> **Identity Conditions:** Even if we only aim to use properties as semantics values for run of the mill predicates, properties must be more finely individuated than sets. And if we hope to use properties as part of a systematic semantic account of belief attributions and other intensional idioms, they will have to be even more finely individuated than intensions. They will have to be (at least) nearly as finely individuated as the linguistic expressions that denote (or express) them.
>
> **Structure:** If we want to account for the behavior of complex predicates or complex singular terms in a systematic way, properties need to have something akin to a logical structure (we will explore the relevant notion of structure in §8.2).
>
> **Modal Status:** The use of properties in many parts of semantics does not obviously require

that properties exist necessarily. But when we turn to portions of English that explicitly involve the alethic modalities and related notions, i.e., when we turn to sentences (like ‘Red is necessarily a color’, ‘7 is necessarily prime’), the most natural accounts will involve properties that exist necessarily.

Epistemic Status: If properties are used to furnish semantic values for a multitude of expressions of a natural language like English or Choctaw, then we will need a lavish realm of properties that includes properties that are not instantiated. If such properties raise epistemological problems, then there will be difficulties explaining how our linguistic behavior, here in the natural world, involves properties we couldn't know much about. Furthermore, the more facts about language we can know *a priori*, the more likely it is that we will need some sort of *a priori* access to properties.

4.3 Naturalistic Ontology

In recent years properties have played a central role in philosophical accounts of scientific realism, measurement, causation, dispositions, and natural laws. This is a less unified set of concerns than those encountered in the previous two subsections, but it is still a clearly recognizable area, and I will call it *naturalistic ontology*. The use of properties in naturalistic ontology is often less formal and more varied than the work in the areas we have examined. I will indicate the flavor of this work by describing several noteworthy treatments of topics in the area.

Scientific Realism

Even quite modest and selective versions of scientific realism are most easily developed with the aid of properties. This is so because they offer a way to account for the following phenomena.

Quantification over Properties

Claims that appear to quantify over properties are common in science.

1. If one organism is fitter than a conspecific, then there is at least one property the first organism has that gives it a greater propensity to reproduce than the second.
2. There are many inherited characteristics, but there are no acquired characteristics that are inherited.
3. Properties and relations measured on an interval scale are invariant under positive linear transformations, but this isn't true of all properties and relations measured on ordinal scales.
4. In a Newtonian world all fundamental ("meaningful") properties are invariant under Galilean transformations, whereas the fundamental properties in a special-relativistic world are those that are invariant under Lorentz transformation.

No one has any idea how to paraphrase most of these claims in a non-quantificational idiom, and they

certainly seem to assert (or deny) the existence of various sorts of properties. The claim that this is in fact precisely what they do explains how they can be meaningful and, in many cases, true.

Functional Properties

Many important properties like *being a simple harmonic oscillator*, *being a gene*, *being an edge detector*, or *being a belief* are often thought to be functional properties. To be a gene, for example, is to play a certain causal role in the transmission of hereditary information, and it is in principle possible for quite disparate physical mechanisms to play this role. To say that something exemplifies a functional property is, roughly, to say that *there are* certain properties that it exemplifies and that together they allow it to play a certain causal role. For example, DNA molecules have certain properties that allow them to transmit genetic information in pretty much in the way described by Mendel's laws. Here again, we have quantifications over properties that seem unavoidable.

Causal Powers

Much explanation in science is causal explanation, and casual explanations often proceed by citing properties of the things involved in causal interactions. For example, electrons repel one another in the way that they do because they have *the same charge* (we will return to this below).

Reduction and Supervenience

A few decades ago claims that one sort of thing was *reducible* to a second were common; e.g., one often heard that the temperature of a gas is reducible to its mean molecular kinetic energy. Nowadays we are more likely to hear that one sort of thing *supervenes* on another: e.g., all biological (or all psychological) features of an organism supervene on its physical properties. Such claims make the best sense if we take them to involve properties. For example the claim that the psychological realm supervenes on the physical realm is plausibly construed as the claim that, necessarily, everything that has any psychological properties also has physical properties and any two things that have exactly the same physical properties will have exactly the same psychological properties. Disputes remain about the best way to spell out the fine print, but almost all of the candidates advert to properties.

Theory Change

Some philosophers of science, most notably Feyerabend and Kuhn, argue that theoretical terms draw their meaning from the theories within which they occur. Hence, they conclude, a change in theory causes a shift in the meanings of all of its constituent terms, and so different theories simply talk about different things. And since Newton's talk of ‘mass’ and Einstein's talk of ‘mass’ are about different things, their theories cannot be rationally compared; the theories are "incommensurable". The common realist rejoinder is that the reference of terms can remain the same even when the surrounding theory shifts (at least as long as it doesn't shift too much). Now it is certainly true that some realists have placed a greater explanatory burden on reference than it can bear. But for this response to work, even in cases of small shifts in theory, terms like ‘mass’ or ‘rest mass’ or ‘mass of 3.4kg’ must refer to something, and the most

plausible candidate for this is a property.

Measurement

Various features of measurement are most easily explained by invoking properties.

Different ways to Measure the Same Thing

Simpler anti-realist theories of measurement (like operationalism) cannot explain how we can use different methods to measure the same thing, e.g., how we can use such different methods to measure lengths and distances in cosmology, geology, histology, and atomic physics. By contrast, the view that measurements aim to discover objective properties can explain this.

Measurement Error is a Fact of Life

In many sciences it is expected that estimates of the magnitude of measurement error will be reported along with measurement results. Indeed, in fields like econometrics and psychometrics, extremely detailed theories of error are always near center stage. But such talk makes little sense unless there is a fact about what a correct measurement would be. Since an object can have one magnitude (e.g., a rest mass of 3kg) at one time and a different magnitude (e.g., a rest mass of 4kg) at another time, the object alone cannot explain this. But it is quite naturally explained by assuming that the object instantiates two different mass properties (namely a rest mass of 3 kg, and a rest mass of 4 kg) at the two different times. It also explains why later techniques for measuring things can be more accurate than earlier methods (e.g., why Atwood's machine allowed him to measure the value of the gravitational constant much more accurately than his predecessors could).

Measurement Units are Often Specified Using Properties

Nowadays measurement units are often specified directly in terms of properties. At one time the meter was specified as the length of the standard meter bar in Paris, But we now specify the meter in terms of something that can in principle be instantiated anywhere in the world, e.g., as *the length* equal to a certain number of wavelengths (in a vacuum) of a particular color of light emitted by krypton 86 atoms.

These facts have led to several adaptations of the representational theory of measurement developed by Suppes and his coworkers to a framework involving properties (Mundy, 1987; Swoyer, 1987). Among other things, these accounts offer characterizations of the algebraic structure of many of the properties involved in measurement.

Causal Powers

Some philosophers have employed properties in reductive accounts of causation (cf. Tooley; 1987; Fales, 1990). It would take us too far afield to explore this work here, but it is worth noting that it is never a

single, undifferentiated amorphous blob of an object (or blob of an event) that makes things happen. It is an object (or event) *with properties*. Furthermore, *how* it affects things depends on what these properties are. The liquid in the glass causes the litmus paper to turn blue because the liquid is an alkaline (and not because the liquid also happens to be blue). The Earth exerts a gravitational force of the moon because of their respective gravitational masses. And because explanations often cite causes, it is not surprising that explanations frequently cite properties: the liquid's being an alkaline explains why it turned the litmus paper blue (this doesn't preclude deeper explanations involving the molecular mechanisms that underlie this process, but they too will typically involve properties (like valence and charge)).

Some causal powers are deterministic: any object with a gravitational mass will exert a certain amount of force on an object with a certain gravitational mass at a certain distance from it. Others are indeterministic: photons can be prepared in a *state* that will give them a 50/50 chance of making it through a polarizer set at a certain angle. In some cases the *only* informative things we can say about a property are what tendencies or powers or capacities it confers on its instances. For example, the things we know about determinate charges have to do with the active and passive powers they confer on particles that instantiate them, their effects on the electromagnetic fields surrounding them, and the like. Thus, two negatively charged particles at a given distance will exert a force with a specific magnitude and direction on each other that depends on their respective charges (monadic properties) and the distance between them (a two-place relation) in accordance with Coulomb's law. Similar points hold for many other properties in science, including mass, momentum, force, electrical resistance, tensile strength, torque, and spin.

Such facts have led some philosophers to claim that properties are essentially dispositional, or even that properties *just are* dispositions. This led to a debate over whether all properties are dispositional (like charge and spin are) or whether some were non-dispositional (perhaps like squareness). The discussion here was considerably clarified by Shoemaker's (1984, p. 210ff) claim that it is linguistic items, rather than *properties*, that are dispositional or not. Some predicates, e.g., ‘fragile’, ‘flexible’, and ‘irascible’ are dispositional, whereas predicates, e.g., ‘square’ and ‘table’ arguably are not. But all properties confer causal powers on their instances; a square peg does not have the capacity to fit into a round hole (below a certain size).

Properties and Powers

Philosophers who focus on the causal or nomological capacities that properties confer on their instances often urge that properties are *identical* just in case they confer *the same* capacities on their instances (e.g., Achinstein, 1974; Armstrong, 1978, Ch. 16; Shoemaker 1984, Ch. 10-11). This general idea leaves us with questions about the relationship between properties and the capacities they bestow, but using fairly intuitive (though not incontrovertible) counting principles for properties and capacities, we can say the following:

> **Different Properties, Same Power:** Different properties can bestow the same powers on their instances. For example, charge and gravitational mass both bestow a power to exert a force on nearby objects (that have the right sorts of properties).

> **Same Property, Different Powers:** A single property can bestow different powers on its instances. For example, a determinate charge like the unit negative charge that characterizes electrons confers an ability to exert an attractive force on positively-charged particles and it confers an ability to exert a repulsive force on negatively-charged particles.

Although the connection between properties and powers is important, it isn't fully understood. Is a capacity an additional sort of property over and above the property that confers it? This sounds unduly complicated, but if this is not the case we need an account of the relationship.

Laws of Nature

Properties have played a central role in several recent accounts of natural laws. I will focus on two accounts that put properties at center stage; hybrids are possible, but the examples discussed here typify much recent work.

N-relation Theories

Laws of nature (e.g., the ideal gas laws, Newton's laws, Shrödinger's equation, Einstein's field equations for general relativity, conservation laws) have several important features, and the task of a philosophical account of laws is to explain how this is so. Different philosophers view different (and sometimes incompatible) features as central to laws, but those who favor what I will call *N-relation theories* agree that laws have (at least most of) the following five features. I will focus primarily on deterministic laws, not because they are more important than probabilistic laws, but because if an account cannot get deterministic laws right, it will have little chance with probabilistic laws.

1. Laws are objective. We don't invent laws, we discover them.
2. Laws have modal force. This shows up when we describe laws (or their implications) using words like ‘must’, ‘require’, ‘preclude’, and ‘impossible’.
3. Laws, unlike accidental generalizations, are confirmed by their instances and underwrite predictions.
4. The line between laws and non-laws is sharp; nomologicality does not come in degrees (this is implicit in the work of many *N*-relation theorists; Armstrong, 1983, p. 71 notes that his account depends on it).
5. Laws have genuine explanatory power. They play a central role in scientific explanation that accidental generalizations cannot.

N-relation theories have been defended by Armstrong (e.g., 1978, 1983), Dretske (1977), Tooley (1977) and others. Their accounts differ in detail, but they share the core idea that laws of nature are relations among properties. A law is a second-order relation of *nomic necessitation (N*, for short) holding among two or more first-order properties. Hence the *logical form* of a statement of a simple law is not ‘All Fs are Gs’; in the case of a law involving two first-order properties, it is a second-order atomic sentence of the

form ‘*N*(F,G)’.

In the more exact sciences these first-order properties (our *F*s and *G*s) will typically be determinate magnitudes like a kinetic energy of 1.6×10^{-2} joule or a force of 1 newton or an electrical resistance of 12.3 ohms (rather than mass or force or resistance simpliciter). Hence the laws specified by an equation (like Newton's second law) are really infinite families of specific laws where each specific, determinate mass *m* (a scalar, and so a monadic property) and total impressed force *f* (a vector, and so a relational property) stand in the *N*-relation to the appropriate relation (vector) of acceleration *a* (= *f/m*).

The Background: *N*-Relation Theories vs. Regularity Theories

The dominant accounts of laws during much of this century were *regularity theories*, and *N*-relation theories were originally devised to avoid perceived shortcomings of these earlier accounts. There are many versions of the regularity theory, but they share the core idea that laws are simply contingent regularities (or the sentences expressing them). On such views there is no *metaphysical* difference between genuine laws and true accidental generalizations (at least accidental generalizations involving purely qualitative predicates or properties) like ‘all cubes of pure gold weigh less than ten tons’ (which I'll assume is true). According to regularity theorists, the only difference between laws and accidental regularities is that laws have some special epistemic or pragmatic or logical trappings (e.g., they contain projectible predicates like ‘rest mass’ rather than ‘grue’ or they form part of a powerful deductive theory). The most prominent version of the regularity theory nowadays is the Ramsey-Lewis account, according to which laws are those universal generalizations that would be part of the overall systematization of our theories about the world that best combines simplicity and strength.

One of the chief attractions of regularity theories is that they have a relatively low epistemological cost. We observe instances of many regularities here in the actual world, and the additional features used to upgrade regularities to laws are not epistemically problematic in any deep way. Indeed, although there are various detailed problems with regularity theories, the major issues between *N*-relation theorists and regularity theorists involve the fundamental ontological tradeoff. According to *N*-relation theorists, regularity theories only achieve their epistemic security by being so weak that they cannot explain the fundamental features of laws. Regularity theorists counter that the *N*-relation is a mysterious bit of metaphysics, and that there is no way we could ever gain epistemic access to it. *N*-relation theorists respond that we should believe in it because it provides the best explanation of the five items on the above list. Is this response plausible? To evaluate it we need to look briefly at how those explanations are supposed to work.

N-relation Theories: Sample Explanations

Objectivity

According to *N*-relation theories, laws are objective because the *N*-relation relates those properties it does quite independently of our language and thought (in the case of properties that don't specifically involve

our language or thought). By contrast, the epistemic and pragmatic features used by regularity theorists to demarcate laws from accidental generalizations are too anthropocentric to account for the objectivity of laws.

Modal Force

Many laws seem to necessitate some things and to preclude others. Pauli's exclusion principle *requires* that two fermions occupy different quantum states. The special theory of relativity *doesn't allow* a signal to be propagated at a velocity exceeding that of light. The laws of thermodynamics show the *impossibility* of perpetual motion machines. Conservation laws assure us that such quantities as angular momentum, mass-energy, and charge *cannot* be created or destroyed. The modal force of laws is also said to manifest itself in the way laws support counterfactuals; had there been a tenth planet, it too would have obeyed Kepler's Laws. But, *N*-relation theorists insist, since regularity theorists forswear everything modal, they can never account for the modal aspects of laws.

Confirmation and Prediction

N-relation theorists often argue that their accounts can, and that regularity theories cannot, explain how laws are confirmed by their instances. *If* laws were mere regularities, then the fact that observed *F*s have been *G*s would give us no reason to conclude that those *F*s we haven't encountered will also be *G*. If the *F*s we have observed are to be *relevant* to our belief that unobserved *F*s are *G*s, then there needs to be *something about* an object's being *F* that requires (or, in the case of probabilistic laws, makes it probable) that it will also be *G*. And if the properties *F* and *G* stand in a nomic relation, then the properties themselves (and not merely their instances) are related in a law-like way. Hence, if *N*-relation accounts are right, there *will* be something about an object's being an *F* that will make it be a *G*, and the examined cases will be related to the unexamined cases in the relevant way.

A Nice Sharp Line

Properties either stand in the *N*-relation or they do not. When they do, we have a law; when they do not, we don't.

Explanation

The accidental regularity that all cubes of gold weigh less than ten tons doesn't explain why any particular cube of gold weighs less than ten tons. But, *N*-relation theorists often argue, if one property nomically necessitates a second, that does explain why anything having the first also has the second.

The Upshot

If *N*-relation accounts are on the right track, there is a reasonably rich realm of properties that is structured by one or more nomic relations. But before drawing this conclusion we should note that *N*-relation theories face difficulties of their own. Indeed, it is unclear whether *N*-relation theories can

successfully explain all of the things they were introduced to explain, but we will focus on two more general difficulties here. (A fuller discussion of the problems for *N*-relation theories can be found in the supplementary document [Difficulties for *N*-relation Accounts of Natural Laws].) First, it is not clear how to extend *N*-relation accounts to deal with several important kinds of laws, most prominently conservation laws and symmetry principles. Second, even in the case of laws that can be coaxed (or crammed) into the *N*-relation scheme, the account involves a highly idealized notion whose connection to the things that go by the name 'law' in labs and research centers is rather remote.

At this point some philosophers propose a distinction between the *current laws of science* and the *true laws of nature*. The former are approximate, idealized and provisional, whereas the later are precise, definite and unchanging. Furthermore, they continue, while it is perfectly respectable for philosophers to discuss the current laws of science, philosophy should also provide an account of the true laws of nature. But although some philosophers propose lists (like the one above) of features that are supposed to characterize the true laws of nature, it is not clear that there are any laws of this sort. At all events, current science doesn't force this conclusion on us, and the claim that there are such laws involves a bit of metaphysical speculation.

Properties, Powers and Laws

If we begin with actual scientific laws, we are likely to come up with quite different features from those on the [list above].

1. Laws almost always involve approximation and idealization Sometimes the idealization is so great that a law is quite inaccurate over parts of the range of phenomena it is supposed to cover (as is the law for the simple pendulum or the general gas laws). Most laws only hold *ceteris paribus*, "other things being equal," but other things rarely are.
2. When we apply a law to a situation, we often use a highly simplified version of the law that everyone acknowledges is false.
3. Laws are not in any straightforward way confirmed by their instances. Actual data and phenomena that provide evidence for a law rarely fit it exactly (even when we discount for measurement error).
4. We often explain things by citing the causal mechanisms and processes they involve, rather than by subsuming them under general laws. For example, we do not explain why all crows are black by saying (in some more idiomatic way) that the *N*-relation holds between the properties *being a crow* and *being black*. We explain it by finding causal (in this case genetic) mechanisms that link the two properties. In other cases we appeal to a deeper theory, e.g., we explain why Kepler's laws hold (to the extent that they do) by deriving (approximations of) them from Newton's laws.
5. The distinction between laws and accidental generalizations is a matter of degree. We often talk as though some laws (e.g., various conservation laws) are very fundamental and robust, while other laws (e.g., Hooke's Law, Boyle's Law, Gresham's Law) are less so.

A philosopher who sees 1-5 as central features of laws will be drawn to an account that is very different

from that proposed by *N*-relation theorists. Far from involving universal (or even precise probabilistic) nomological relations, actual laws are idealized, approximate, and limited in scope (often applying only to highly artificial systems created in laboratories or even just to simplified models of real systems).

When *N*-relation theories first appeared on the scene much of their appeal was that they promised a better account of the objectivity and (perhaps) the modal status of laws than regularity theories could provide. But it is now possible to discern the beginnings of an account that explains these things (to the limited degree that they hold) and that also explains how actual laws work. I will quickly sketch a generic version of such an account here (several versions are in the air, but most of them owe a large debt to Cartwright, 1983; 1989).

We have already noted that (at least many) properties confer causal capacities and tendencies on their instances. For example, electrically charged particles have a capacity to exert forces on other particles and to affect an electromagnetic field around them *in virtue of* the property of having a specific, determinate charge. This is a perfectly objective fact, and it has a certain modal force (if the particles had moved away from each other, the forces would have fallen off with the square of the distance between them). This suggests the view that laws result from the operations of capacities (including probabilistic capacities). Laws tell us what happens when we shield off (or hold constant) the influence of other capacities and allow a single capacity (or just a few capacities) to work without interference. In a few cases we can shield the operation of a single capacity from outside influences in a way that allows us to make fairly precise and accurate predictions, and cases like this may approximate the *N*-relation theorist's conception of a law. But most laws, and most applications of laws, aren't like this. The detailed behavior of most things, including many relatively simple physical systems, results from the joint operation of many capacities or tendencies, and often it cannot be predicted, or even explained, on the basis of such laws. Accounts like Cartwright's take science at face value and they leave room for laws in fields other than basic physics. But for our purposes the most important thing about them is that they, like *N*-relation theories, place properties at center stage.

Lessons About Properties

The work discussed in this subsection suggests that properties include determinate physical magnitudes like *being a mass of 3.7 kg* and *being an electrical resistance of 7 ohms*. Furthermore, such properties typically form families of ordered determinates (e.g., the family of determinate masses) that have a definite algebraic structure (Mundy, 1987; Swoyer, 1987). It also suggests that a fundamental feature of at least many properties is that they confer causal capacities on their instances. Work on naturalistic ontology doesn't entail detailed answers to every question about the nature of properties, but it does suggest answers to some of them.

> **Existence Conditions:** A natural, though not inevitable, conclusion to draw from the work discussed in this subsection is that properties exist only if they confer causal or nomological capacities on their instances. For properties: to be is to (be able to) confer causal capacities.

Identity Conditions: The most natural conclusion to draw here is that properties are identical just in case they confer exactly the same causal powers on their instances.

Structure: If *N*-relation theories are right, the realm of properties is structured in at least the minimal sense that many pairs of properties stand in one or more higher-order nomological relations. Properties are also related to the causal powers they confer on their instances in some intimate, though not clearly understood, way.

Modal Status: If laws of nature are metaphysically necessary, then properties that actually stand in the *N*-relation stand in that relation in all possible worlds in which they exist. The fact that properties confer causal powers on their instances is also naturally understood as the claim that the instances of a property have those powers in all possible worlds in which that property exists.

Epistemic Status: Philosophers who employ properties to provide explanations in naturalistic ontology typically hold that we learn about properties empirically. On some accounts all properties are instantiated, and we learn about them because their instances affect our sensory apparatus or our measuring instruments. On other accounts some properties are uninstantiated, but they are related to properties that are instantiated in systematic ways. For example, a specific determinate mass (e.g., 4 kg) might be uninstantiated, but we can describe it quite precisely (as twice as great a mass as 2 kg, which is, let us suppose, exemplified). Furthermore, we can say what causal powers it would have conferred on its instances, had it had any (e.g., we can say what gravitational force its instances would have exerted on a 2 kg object 5 meters away).

At this point it is useful to step back to note the fundamental way in which the *general* conception of properties discussed in this subsection differs from many of the conceptions discussed earlier. On those earlier conceptions at least many properties are causally inert, other-worldly, abstract entities that exist outside space and time; they are timeless, necessary beings, and since we cannot come into causal contact with them, our knowledge of them is problematic.

By contrast, the view that emerges from much of the work in naturalistic ontology treats properties as contingent beings that are intimately related to the causal, spatio-temporal order, and we learn what properties there are and what they are like through empirical investigation. Such properties are not much like meanings or concepts, and so it is possible to discover that a property conceived of in one way (e.g., the property of being water) is identical with a property conceived in some quite different way (e.g., the property of being H_2O). It might be misleading to call such properties ‘concrete’ (the standard antonym of the slippery word ‘abstract’), but it isn't quite right to call them ‘abstract’ either. Indeed, the stark dichotomy between the abstract and concrete is probably too simple to be useful here.

5 Existence Conditions

What properties are there? Under what conditions does a property exist? In formal accounts--those modeled on axiomatic set theory or axiomatic treatments of other mathematical entities--the goal is typically to find formal principles (like comprehension schemas) that state sufficient (and, with luck, necessary) conditions for the existence of properties. But the basic issues about the existence conditions of properties are not really formal ones. Indeed, views about their existence conditions typically derive from an interplay of views about the explanatory tasks of properties and legitimate constraints on philosophical explanation.

We can view the array of views about the existence conditions of properties as a continuum, with claims that the realm of properties is sparse over on the right (conservative) end and claims that it is bountiful over on the left (liberal) end.

5.1 Minimalism

According to minimalist conceptions of properties, the realm of properties is sparsely populated. This is a comparative claim (it is more thinly populated than many realists suppose), rather than a claim about cardinality. Indeed, a minimalist could hold that there is a large infinite number of properties, say that there are at least as many properties as real numbers. This would be a natural view, for example, for a philosopher who thought that each value of a physical magnitude is a separate property and that field theories of such properties as gravitational potentials are correct in their claim that the field intensity drops off continuously as we move away from the source of the field.

The best-known contemporary exponent of minimalism is David Armstrong (e.g., 1978, 1984, 1997), though it has also been defended by others (e.g., Swoyer, 1996). Specific reductionist motivations (e.g., a commitment to physicalism) can lead to minimalism, but here we will focus on more general motivations. These motivations typically involve some combination of the view that everything that exists at all exists in space and time (or space-time), a desire for epistemic security, and a distrust of modal notions like necessity. Hence, a minimalist is likely to subscribe to at least most of the following four principles.

1. The Principle of Instantiation

The *principle of instantiation* says that there are no uninstantiated properties. For properties: to be is to be exemplified. Taken alone the principle of instantiation doesn't enforce a strong version of minimalism, since it might be that a wide array of properties are exemplified. For example, someone who thinks that numbers or individual essences or other abstract objects exist would doubtless think that a vast number of properties are exemplified. So it is useful to distinguish two versions of the principle of instantiation.

> **Weak Instantiation:** All properties are instantiated; there are no uninstantiated properties.
>
> **Strong Instantiation:** All properties are instantiated by things that exist in space and time

(or, if properties can themselves instantiate properties, each property is part of a descending chain of instantiations that bottoms out in individuals in space and time).

Armstrong (1978) holds that properties enjoy a timeless sort of existence; *if* a property is ever instantiated, then it *always* exists. A more rigorous minimalism holds that properties are mortal; a property only exists *when* it is exemplified. This account has an admirable purity about it, but it is hard pressed to explain very much; for example, if laws are relations among properties, then a law would seem to come and go as the properties involved did.

2. Properties are Contingent Beings

Philosophers who subscribe to the strong principle of instantiation are almost certain to hold that *properties are contingent beings*. It is a contingent matter just which individuals exist and what properties they happen to exemplify, so it is a contingent matter what properties there are.

3. The Empirical Conception of Properties

A natural consequence of the view that properties are contingent beings is that questions about which properties exist are empirical. There are no logical or conceptual or any other *a priori* methods to determine which properties exist.

4. Properties are Coarse Grained

Those who hold that properties are very finely individuated will be inclined to hold that the realm of properties is fairly bountiful. For example, if the relation of *loving* and the converse of its converse (and the converse of the converse of that, and so on) are distinct, then properties will be plentiful. Minimalists, by contrast, are more likely to hold that properties are identical just in case they necessarily have the same instances or just in case they bestow the same causal powers on their instances. On these views the converse of the converse of a binary relation will just be that relation itself (we will return to this matter in the section on identity conditions of properties).

Locations?

The strong principle of instantiation opens the door to the claim that properties are literally located in their instances. This is a version of Medieval philosophers' doctrine of *universalia in rebus*, which was contrasted with the picture of *universalia ante rem*, the view that properties are transcendent beings that exist apart from their instances. With properties firmly rooted here in the spatio-temporal world, it may seem less mysterious how we could learn about them, talk about them, and use them to provide illuminating explanations. For it isn't some weird, other-worldly entity that explains why this apple is red; it is something *in* the apple, some aspect of it, that accounts for this. It is easier, however, to think of monadic properties as located in their instances than it is to view relations in this way (this may be why Aristotle and the moderate realists of the middle ages viewed a relation as an accident that inheres in a

single thing). Nevertheless, the general feeling that transcendent properties couldn't explain anything about their instances has figured prominently in many debates over properties.

Minimalists must pay a price for their epistemic security (there's no escaping the fundamental ontological tradeoff). They will have little hope of finding enough properties for a semantic account of even a modest fragment of any natural language and they will be hard pressed (though Armstrong, 1997, does try) to use properties to account for phenomena in the philosophy of mathematics. Minimalists may not be greatly bothered by this, however, for many of them are primarily concerned with issues in naturalistic ontology.

5.2 Maximalism

At the other, left, end of the spectrum we find maximalist conceptions of properties. Borrowing a term from Arthur Lovejoy, maximalists argue that properties obey a *principle of plenitude*. Every property that could possibly exist *does* exist. For properties: To be is to be possible (Linsky & Zalta, 1995; cf. Jubien, 1989). If one accepts the view that properties are necessary beings, then it is a simple modal fact that if a property is possible it is necessary and, hence, actual.

Just as the principle of instantiation alone does not guarantee minimalism, the principle of plenitude alone does not guarantee maximalism. One can endorse the former while holding that all sorts of properties are instantiated, and one can endorse the latter by holding that very few properties are possible (an actualist who subscribed to the strong principle of instantiation might hold this). So to get to the maximalist end of the spectrum we need to add the claim that a vast array of properties is possible. Various formal principles, e.g., a strong comprehension principle (e.g., Zalta, 1988) and axioms ensuring very finely-individuated properties (e.g., Bealer, 1982, p. 65; Menzel, 1986, p. 38) are two formal ways to achieve this.

Maximalist accounts are often propounded by philosophers who want to explain meaning and mental content, but since such accounts postulate so many properties that maximalists have the resources to offer accounts of other things (e.g., phenomena in the foundations of mathematics), and many do. Indeed, the great strength of maximalism is that its enormously rich ontology offers the resources to explain all sorts of things.

Epistemology is the Achilles' heel of maximalism. At least some philosophers find it difficult to see how our minds could make epistemic contact (and how our words could make semantic contact) with entities lying outside the spatio-temporal, causal order. But maximalism has its advantages. Those maximalists who are untroubled by epistemic angst typically remain maximalists. By contrast, philosophers who begin as minimalists sometimes feel pressure to move to a richer conception of properties, either to extend their explanations to cover more phenomena or, sometimes, even just to adequately explain the things they started out trying to explain (e.g., Armstrong's more recent work is somewhat less minimalist than his earliest work).

5.3 Centrism

There is a large middle ground between extreme minimalism and extreme maximalism. For example, several philosophers primarily concerned with physical ontology have urged that a limited number of uninstantiated properties are needed to account for features of measurement (Mundy, 1987), vectors (Bigelow and Pargetter, 1990, p. 77), or natural laws (Tooley, 1987). Such accounts can, like minimalism, treat properties as contingent, fairly coarsely individuated, and too sparse to satisfy any general comprehension principles (e.g., they may deny that there are negative or disjunctive properties). One can also arrive at a centrist position by endorsing a comprehension principle but adding that it only guarantees the existence of properties built up from an initial, sparse, stock of simple properties (cf. Bealer, 1994, p. 167).

Being moderate isn't always easy, and it can be difficult to stake out a position in the center that doesn't appear arbitrary. Once *any* uninstantiated properties are admitted, we are in much the same epistemological boat as the maximalist. No doubt the minimalist will see this as a reason to reject any uninstantiated properties, while the maximalist (who believes that epistemological problems can be overcome) will see it as a reason to admit as many as possible.

5.4 Dual-Entity Accounts

There is some reason to think that accounts in different fields (e.g., semantics and natural ontology) may call for entities with different identity conditions; for example, semantics requires very finely individuated properties whereas naturalist ontology may need more coarsely individuated ones. If this is so, then no single kind of entity could do both kinds of jobs. The minimalist is likely to conclude that it is a mistake to employ properties in semantics. But less squeamish philosophers may instead conclude that there are (at least) two different sorts of property-like entities. Bealer's (1982) qualities and concepts and Lewis's (1986) sparse and abundant properties are examples of this approach. But this happy hybrid won't satisfy everyone, since minimalists (and some centrists) will reject the view that there are any concepts or abundant properties.

Summary

Disputes over the existence conditions of properties splinter into several related, but distinct, issues.

1. Instantiation issues: Must a property be exemplified to exist?
2. Localization Issues: Do exemplified properties exist in space and time (namely where they are instantiated)?
3. Modal issues: Are properties contingent beings or are at least some necessary beings?
4. Epistemological issues: Is the only way to discover the existence of properties though empirical means?
5. Individuation issues: How finely individuated are properties?

Minimalists hold that *all* properties are contingent beings, that they must be exemplified in space and

time to exist, that we can only discover their existence empirically, and that they are fairly coarsely individuated. Some minimalists also hold that they exist in those locations where they are instantiated. Maximalists reject all of these views. These two sets of views form fairly natural packages, but other combinations are possible, and they lead to views falling between the two extremes.

6 Identity Conditions

What are the identity conditions for properties? An answer would give us necessary and sufficient conditions for the properties *x* and *y* to be one and the same property. Another way to pose the question is to ask how finely individuated properties are, and here we find a spectrum of views.

- **Infra-coarse:** Properties with the same extension are the same properties (this holds for Frege's concepts, but all contemporary property theories reject this claim; it is included simply as a point of reference).
- **Medium coarse:** Properties are identical just in case they necessarily have the same extension.
- **Medium Fine:**
  - Properties are identical just in case they confer the same causal or, more generally, the same nomological powers on their instances (i.e., they are identical if they play the same functional role), or
  - Properties are identical just in case they are encoded by exactly the same abstract objects (Zalta)
- **Ultra-fine:** Properties are individuated almost as finely as the linguistic expressions that express them. A natural way to work this out is to develop an account of the analysis of a property and to hold that properties are identical just in case they have the same analysis (cf. Bealer's account of concepts; Menzel, 1993).

On most medium-fine views, formal considerations alone do not determine identity conditions for properties.

6.1 Necessary Coextension

Probably the best-know candidate for an identity condition for properties is necessary coextensiveness. This seems to transpose the identity conditions for sets into an appropriately intensional key, and this is precisely how identity conditions for properties work in accounts that treat them as intensions (as functions from possible worlds to objects therein). Bealer also views this as the identity condition for his sparse properties, qualities and connections (though he is undogmatic about this).

Although necessary coextension may be the most-discussed candidate identity condition for properties, many realists reject it because it doesn't comport well with the explanations they want to develop. Identity conditions don't matter greatly when the aim is simply to explain mathematical phenomena; even extensional entities like sets could do that job, so we don't need necessary coextension as an identity

condition here. This proposal is also in tension with the picture that properties are individuated by their functional roles, at least on the assumption that necessarily coextensive properties can confer different causal powers on their instances (Sober, 1982, contains a strong argument that this can happen, though the jury is probably still out on this issue). And in semantics we need hyper-intensional properties that are individuated much more finely than the necessary-coextension condition allows.

6.2 Functional Role

The view that properties are identical just in case they confer the same causal, or more generally, the same nomological or functional roles on their instances has been endorsed by various philosophers who work primarily in scientific ontology. On this conception, there are few, if any, purely formal identity conditions for properties (unless, as seems unlikely, someone devises a purely formal account of causal roles). One cost of this view is that the notion of a causal role and the relationship between such roles and properties is not completely clear.

6.3 Property Identity in Terms of Encoding

We have encountered all of the major current views about the identity conditions of properties except for one in previous sections, so we will go into it in a bit more detail here. The *encoding account of property identity*, proposed in Zalta (1983; 1988), is developed in the context of a rich theory of properties that goes along with a rich theory of abstract objects. In this theory, ordinary objects (like Bill Clinton) exist, exemplify properties, but cannot encode properties. By contrast (on the most common interpretation of his system), abstract objects (like Pegasus and the Euclidean triangle) exist necessarily, but they necessarily fail to have a spatio-temporal location. Abstract objects encode, as well as exemplify, properties; indeed, an abstract object is *constituted* by the properties it encodes. For example, the abstract object the Euclidean triangle encodes all and only those properties implied by being a triangle of Euclidean geometry (e.g., being a closed three-side plane figure whose interior angles sum to 180 degrees). This abstract object also exemplifies properties, e.g., being mentioned in all textbooks on plane geometry.

The metaphysical theory of abstract objects is linked to our actual thought and talk by the bridge principle that the English copula is ambiguous; sometimes ‘is’ means ‘exemplifies’, sometimes ‘encodes’. The existence condition for abstract objects is given by a comprehension schema according to which there is (necessarily) a unique abstract object that encodes just those properties satisfying each condition on properties specifiable in the language of the theory, and abstract objects are identical just in case they encode exactly the same properties. More importantly, for current purposes, properties are identical just in case they are, necessarily and always, encoded by exactly the same individuals.

On this account, properties that necessarily have the same *encoding extensions* are *identical*, but properties that necessarily have the same *exemplification extensions* may be *distinct*. To see the difference, note that the property of being a round square and the property of being a round triangle necessarily have the same exemplification extension. Hence, accounts (like those noted in §6.3) that treat

necessary (exemplification) coextension as sufficient for identity tell us that they are one and the same property. But since these properties have different encoding extensions, the present account treats them as distinct. One can even make this work without any actual abstract objects, though the nonidentity of two properties would still require that there *could* have been an abstract object that encodes one but not the other. This is one of the few novel accounts of property identity to be proposed in recent decades. It has the virtue of being part of a detailed theory that has been employed to explain a wide range of phenomena, and it expresses the identity conditions for properties in terms of one of their most fundamental features, namely that they are predicable entities. The price is that it requires us to hold that there are two modes of predication and that there are, or at least that there could have been, abstract objects.

6.4 Ultra-fine Properties

The view that properties have ultra-fine identity conditions is typically developed in the context of a rich formal theory of properties. One could mandate fine-grained identity conditions by brute force, e.g., by laying down axioms that each set of objects is in the extension of more than one property, or in the extension of many different properties. But the intuitive idea behind property theories tailored to semantics is that there are "compound properties" which are built up from simpler properties by logical operations akin to conjunction, negation, and so on. On such accounts the property *being red and square* is distinct (because built up in a different way) from the property *being square and red*. Similarly, the converse of the converse of a two-place relation is distinct from that relation itself.

Such accounts may be well-suited for explaining strongly intensional phenomena (like belief sentences or mental content), but they also raise certain questions. For example, what is the difference between the property *being red and square* and the distinct property *being square and red*, and what allows us to link the right complex predicate (say 'is red and square') to the right property (*being red and square*) rather than to the wrong one (*being square and red*)? If properties literally had parts, the answer might be that the arrangements of things in the two properties is different (e.g., *being red* comes "first" in *being red and square*). Explaining what such structural differences amount to would not be easy, but at least such differences might point to the beginnings of a solution. By contrast, if properties lack genuine internal structure, it is less clear how an account of the difference between *being red and square* and *being square and red* would even begin. We will return briefly to such matters in the final section.

7 Kinds of Properties

Most realists agree that there are various sorts of properties, and in this section we will review the main kinds of properties they have proposed. But many realists are also selective; they believe that some, but not all, of these kinds of properties exist. Indeed, *almost none* of the putative kinds of properties discussed here is accepted by all realists, but to avoid constant qualifications (like 'putative kind of property') I will present each sort of property as though it were unproblematic.

First-order vs. Higher-order Properties

The first set of issues we will examine involve the most fundamental logical or structural features of properties. We will begin with a picture of a hierarchy of properties arranged according to order. First-order properties and relations are those that can only be instantiated by individuals. For example *redness* can be instantiated by the apple on my desk and *being married to* can be instantiated by Bill and Hillary, but no properties can be red or married. It is natural to suppose, however, that at least many first-order properties and relations can themselves have properties and relations. For example, *redness* might be thought to exemplify the property of *being a color* and *being married to* might be thought to exemplify the property of *being a symmetrical relation*. Once we think of second-order properties, it is natural to wonder whether there are third-order properties (properties of second- or, perhaps in cumulative fashion, of second- *and* first-order properties), and so on up through ever-higher orders.

This metaphysical picture finds a formal parallel in higher-order logics. On one common system of classification, we move from familiar first-order logic to second-order logic by adding first-order variables, from second- to third-order logic by adding second-order constants, from third- to fourth-order logic by adding second-order variables, and so on up, alternating constants and variables at successive steps.

Realists differ over which niches in this proposed hierarchy of orders are occupied. Proponents of the empirical conception of properties will hold that it is an empirical question whether there are second- or forth- or fifty-seventh-order properties. The issue for them is likely to be whether putative higher-order properties confer any causal powers on their instances over and above those already conferred by lower-order properties. But it is also possible to have less empirically motivated views about which parts of the hierarchy are occupied.

Elementarism (Bergmann, 1968) is the view that there are first-order properties but that there are no properties of any higher-order. There are first-order properties like various shades of red, but there is no higher-order property (like *being a color*) that such properties share nor are they related by any higher-order relations (like *being darker than*).

Elementarism has sometimes been defended by appealing to something like Russell's *principle of acquaintance*, the tenet that only things with which we are acquainted should be thought to exist, together with the claim that we are acquainted with first-order properties but not with those of any higher orders. To the extent that first-order properties are able to perform all of the tasks that properties are called on to do, elementarism could also be defended on grounds of parsimony. But it is now widely acknowledged, even by minimalists, that at the very least some higher-order relations are needed to confer structure on first-order properties.

Self-predication and Theories of Types

In May of 1901 Russell discovered his famous paradox. If every predicative expression determines or corresponds to a property, then the expressions 'is a property that does not instantiate itself' should do so. This raises the question: does this property instantiate itself? Suppose that it *does*. Then it is a property that does not instantiate itself; so if it does instantiate itself, it doesn't instantiate itself. Now suppose that it does *not* instantiate itself. Then it is one of those properties that does not instantiate itself; so it does instantiate itself. Such a property, which instantiates itself if and only if it does not instantiate itself, cannot exist (on pain of contradiction). This led Russell to introduce a theory of types which institutes a total ban on self-exemplification by a strict segregation of properties into orders (his account is actually even more restrictive than this; see the entry on Russell's paradox for details).

Untyped Conceptions of Properties

Russell's reaction seems extreme, because many cases of self-exemplification are innocuous. Furthermore, realists who are not minimalists or conservative centrists are likely to think that self-exemplification is common. For example, the property of being a property is itself a property, so it exemplifies itself. There also seem to be transcendental properties and relations. A transcendental relation like *thinks about* is one that can relate quite different types of things: Hans can think about Vienna and he can think about *triangularity*. But typed theories cannot accommodate transcendental properties without several epicycles.

Several recent accounts (e.g., Bealer, 1982; Menzel, 1993) treat properties as entities that can exemplify themselves. From this perspective, the picture of a hierarchy of orders is fundamentally misguided; there are simply properties (which can be exemplified--in many cases by other properties, even by themselves) and individuals (which cannot be exemplified). One challenge here is to develop formal accounts that allow as much self-exemplification as possible without teetering over the brink into paradox. In formal systems where abstract singular terms or predicates may (but need not) denote properties (cf. Swoyer, 1998), formal counterparts of (complex) predicates like 'being a property that does not exemplify itself' could exist in the object language without denoting properties; from this perspective Russell's paradox would merely show that this predicate lacked a denotation, rather than that the logic was inconsistent.

Relations

We have treated relations as properties (with more than one argument place); for example the properties of *loving* and *being shorter than* are two-place relations, that of being in *between* (two other things) is a three-place relation, and so on. On abundant conceptions of properties, there are relations of every finite number of argument places, but on sparse conceptions it is an empirical question whether there are relations of any particular degree (i.e., with any particular number of argument places). What we think of as genuine relations were not recognized by philosophers until about a century and a half ago (with the work of DeMorgan, Schroeder, and Peirce and, somewhat later, Russell). Until then relations were treated as a special sort of monadic property (when they were acknowledged at all).

We have seen how several selective realisms focus on the hierarchy of orders, but selective realisms can also focus on the *degree* (the number of argument places) of relations. Leibniz argued that relations could be reduced to monadic properties (though he never really explained just how this was to work) and so were dispensable. Some philosophers still hold that relations supervene on the monadic properties of their relata in a very strong sense that shows that relations are not actually real (some trope theorists hold this view; it is defended at length in Fisk, 1972). But no one has been able to show that all relations do supervene on monadic properties, and there are strong reasons for thinking that at least some sorts of relations, e.g., spatio-temporal ones, do not. Hence, most contemporary realists hold that there are genuine relations.

Other selective realisms are possible. For example, in contrast with Leibniz's view one might hold that there are relations but no monadic properties (this view is sometimes attributed, with very little textual support, to Peirce). And Armstrong (1978, ch. 24) proposes the tentative hypothesis that there are first- and second-level monadic properties, but no monadic properties of any higher-level.

Fixed-degree vs. Multigrade Properties

Many predicates are *multigrade* or *variably polyadic*; they can be true of various numbers of things. For example, the predicate ‘robbed a bank together’ is true of Bonnie and Clyde, Ma Barker and her two boys, Patti Hearst and three members of the Symbionese Liberation Army, and so on. Multigrade predicates are very common (e.g., ‘work well together’, ‘conspired to commit murder’, ‘are lovers’). Some of them can be analyzed as conjunctions of fixed-degree predicates, but many of them cannot. Standard logic does not accommodate multigrade predicates, but they are very common, and if the goal is to use properties as semantic values of English predicates, then multigrade properties are needed. They have also been used in naturalistic ontology in an ingenious treatment of measurement (Mundy, 1989). A truly flexible account of properties would abandon both the restrictive hierarchy of orders and the equally restrictive view that all properties come with a fixed number of argument places, but as yet little work of this sort has been done.

Propositions

In ancient and Medieval times propositions were not seen as a special kind of property (in those days philosophers didn't even recognize genuine autonomous relations), and many contemporary philosophers

who focus on physical ontology or philosophy of mathematics do not regard propositions as a kind of property (many of them doubt that there are any such things). But those who work on the semantics of natural language often postulate the existence of propositions, noting that we can think of them as a limiting case of a property. Consider a two-place property like *loves* and think of plugging one of its open places up with Darla to obtain the one-place property *loves Darla*. If we can do this, it is sometimes argued, then we can plug the remaining (last) open place up with Sam to get the zero-place property, or proposition, *that Sam loves Darla*.

Structured vs. Unstructured Properties

Some philosophers (e.g., Grossman, 1983, §§58-61) argue that all properties are simple. Others argue that there is a distinction between *simple properties* and *compound properties*, that some compound properties exist, and that they have a structure that involves or incorporates simpler properties. Properties might have different sorts of structure, including various sorts of algebraic or logical structure. Because such issues often arise in connection with formal accounts of properties, this issue is discussed in the section on formal theories of properties.

Instantiation

If instantiation or exemplification is just another run-of-the-mill relation, it appears to lead to a vicious regress. This is often known as *Bradley's regress*, although it is doubtful that Bradley himself had this particular regress in mind. The construal of the Bradley's regress that has passed into the literature goes like this. Suppose that the individual a has the property F. For a to instantiate F it must be *linked to F* by a relation of instantiation, I. But (here's where the trouble begins), this requires a further pair of relations, R_1 and R_2, one to connect a to I and a second to connect I to F. This in turn requires four additional relations to bind R_1 and R_2 to the things that they are supposed to relate, then eight further relations to fasten these four relations to their relata, and so on without end. It is sometimes suggested that the regress is innocuous, but the problem isn't simply that there is a regress. The problem is that at each "stage" further relations are required, but they are *never* able to link their would-be relata. The difficulty is that nothing *ever* gets connected to anything else.

The only way to avoid this difficulty is to insist that instantiation is not a relation, at least not a normal one. Some philosophers hold that it is a *sui generis* linkage that hooks things up without intermediaries. Strawson (1959), following W. E. Johnson, calls it a *non-relational tie*; others stress that it is a mode of predication. It may even be that there is no such thing as instantiation at all and that talk of it is just a misleading figure of speech. At this point it is natural to resort to metaphors like Frege's claim that properties have gaps that can be filled by objects or the early Wittgenstein's suggestion (if we read him as a realist about properties) that objects and properties can be hooked together like links in a chain. Broad likened instantiation to Metaphysical Glue, noting that when we glue two sheets of paper together we don't need additional glue, or mortar, or some other adhesive to bind the glue to the paper (Broad 1933, p.85). Glue just sticks. And instantiation just relates. It is metaphysically self-adhesive.

Particularizing Properties

Some properties are metaphysical analogues of count nouns. They have been called *sortal properties* (by Strawson) and *particularizing properties* (by Armstrong), but the ideas involved here have a long history. Strawson borrows the word 'sortal' from Locke, and at least some particularizing properties correspond closely to Aristotle's secondary substances. Particularizing properties provide counting principles, or principles on identity, in the sense that they allow us to count objects. For example, the properties of *being a table* and *being a cat* are particularizing properties; there are definite facts of the matter as to how many tables are in the kitchen and how many cats are on those tables. There are also properties, e.g., *intervention*, *bombing*, that particularize events.

Characterizing Properties

Particularizing properties are naturally contrasted with *characterizing properties*. Characterizing properties like *redness* and *triangularity* do not divide the world up into a definite number of things. To the extent that a property like *redness* seems to allow us to count red things, it is because we are relying on the umbrella count noun 'thing' to help with the count.

Mass Properties

Particularizing properties may also be contrasted with *mass properties*. These are properties, like *water*, *gold*, and *furniture*, that apply to stuff. Like characterizing properties, mass properties do not divide the world up into definite numbers of things, but many characterizing properties apply to individuals, whereas mass properties apply to stuff. It was noted above that different sorts of linguistic categories that might correspond to important ontological distinctions are run together we represent all of them as predicates of a formal language. It now appears, for example, that common nouns express particularizing properties, while adjectives typically express characterizing properties.

Genus and Species

Although the notions of *genus* and *species* play a relatively small role in contemporary metaphysics, they figured prominently in Aristotle's philosophy and in the many centuries of work inspired by it. When we construe these notions as properties (rather than as linguistic expressions), a genus is a general property and a species is a more specific subtype of it. The distinction is typically thought to be a relative one: *being a mammal* is a species relative to the genus *being an animal*, but it is a genus relative to the species *being a donkey*. It has usually been assumed that in such chains there is a top-most, absolute genus, and a bottom-most, absolute species.

It was traditionally supposed that a species could be uniquely specified or defined in terms of a genus and a differentia. For example, the property *being a human* is completely determined by the properties *being an animal* (genus) and *being rational* (differentia). It is difficult, by today's lights, to draw a principled distinction between genera and differentiae, but the idea that species properties are compound,

conjunctive properties remains a natural one. For example, the property of *being a human* might be identified with the conjunctive property *being a human and being rational*. But it is now rarely assumed, as it was for many centuries, that all compound properties are conjunctive.

Determinables and Determinates

The concepts of *determinables* and *determinates* were popularized by the Cambridge philosopher W. E. Johnson. Properties like *color* and *shape* are determinables, while more specific versions of these properties (like *redness* and *octagonality*) are determinates. Like the distinction between genus and species, the distinction between determinables and determinates is a relative one; redness is a determinate with respect to color but a determinable with respect to specific shades of red. The hierarchy is generally thought to bottom out, however, in completely specific, absolute determinates.

Species are often thought to be definable in terms of a genus and a differentia. But determinates are not definable in terms of a determinable and a differentia; indeed, they are not conjunctive properties of any obvious sort. Determinates under the same determinable are incompatible; nothing can instantiate both of them at the same time, and anything that exemplifies a determinate must exemplify its determinables as well. The distinction between determinables and determinates has played a larger role in recent metaphysics than the more venerable distinction between genus and species. For example, much recent work in naturalistic ontology treats physical magnitudes as absolute determinate properties (like *being a mass of 3 kg* or *being a force of 17 newtons*) falling under determinables like *mass* and *force*.

Any object that instantiates a determinate (e.g. red) must have the corresponding determinable (e.g., color), and Armstrong has raised the question whether determinables are genuine properties or whether we simply apply determinable predicates to things on the basis of the determinate properties that they have. The determinable properties of a thing (if there are any), are necessarily supervenient on the determinates of the thing, in the sense that two things that have exactly the same determinates must also have exactly the same determinables. For example, if two things exemplify the same determinate mass, then both must have a mass. Armstrong (1997, p. 45) urges that this issue is part of a more general issue as to whether necessarily supervenient properties are anything over and above the properties on which they supervene. His answer is that they are not; they are a "metaphysical free lunch." He offers little argument for this claim, however, and many philosophers would demur.

Natural Kinds

Natural Kind Properties are important properties that carve nature at its natural joints. Paradigms include the property of being a specific sort of elementary particle (e.g., the property of being a neutron), chemical element (e.g., the property of being gold), and biological species (e.g., the property of being a jackal). Natural kinds are often contrasted with artificial kinds (e.g., being a central processing unit).

In recent years a good deal of work has been done on the semantics of natural kind terms (involving such issues as whether they are rigid designators). Less work has been done on the ontology of natural kinds,

but it is clear that it is most plausible to speak of natural kinds in those cases where something has what Locke called a *real essence* (in the way that elementary particles or chemical elements probably do). In these cases it seems plausible to suppose that natural kind properties are compound properties that involve simpler properties (e.g., the quantum numbers, for elementary particles; being made of simpler parts standing in specific relations in the way that chemical elements are made up of atoms related by chemical bondings).

The distinctions between natural and artificial kinds and that between particularizing and mass properties are orthogonal to each other. Some natural kind properties, e.g., *being a dog*, are particularizing while others, e.g., *gold*, are not. Likewise, some artificial properties, e.g., *being a table*, are particularizing while others, e.g., *furniture*, are not. The chief issue here is whether there are any natural kinds or whether our classifications are primarily a matter of cultural and linguistic conventions that represent just one of many ways of classifying things (so that joints are a result of the way that we happen to carve things up).

Purely Qualitative Properties

Some properties involve or incorporate particulars. The properties of *being identical with Harry* and *being in love with Harry* involve Harry. Even those who think that lots of properties exist necessarily often believe that non-qualitative properties like this are contingent; they depend upon Harry, and they only exist in circumstances in which he exists. By contrast, purely qualitative properties (like *being a unit negative charge* or *being in love*) do not involve individuals in this way. The distinction between properties that are purely qualitative and those that are not is usually easy to draw in practice, but a precise characterization of it is elusive.

Essential Properties and Internal Relations

A (monadic) property is an essential property of an individual just in case that individual has the property in every possible circumstance in which the individual exists. Essential properties are contrasted with accidental properties, properties that things just happen, quite contingently, to have. My car is red but it could have been blue (had I painted it), so its color is an accidental property. It is doubtless an essential property of my car that it is extended, but interesting examples of essential properties are more controversial--so controversial that some philosophers have doubted whether there are any. It is sometimes suggested, though, that if something is a member of a natural kind, then being a member of that kind is essential to it; for example, *being human* is an essential property of Saul Kripke.

The phrase ‘internal relation’ has been used in different ways, but it is often used as the relational analogue of an essential (monadic) property. For example, if *a* bears the relation *R* to *b*, then *R* internally relates *a* to *b* just in case *a* bears this relation to *b* in every possible circumstance in which they both exist. Relations that are not internal, that contingently link their relata (the things they relate), are external. Bill and Hillary are married, but they might not have been, so this relation between them is external. By contrast, some philosophers have suggested that the relation *being a biological parent of* is an internal

relation. In every world in which Bill and Chelsea both exist, Bill is her father. If this is correct, then the relational property, *being a child of Bill* is essential to Chelsea, but *being the father of Chelsea* is not essential to Bill (he and Hillary might never have met, in which case they would not have had Chelsea).

Intrinsic vs. Extrinsic Properties

Some properties are instantiated by individuals because of the relations they bear to other things. For example the property *being married* is instantiated by Bill Clinton because he is *married to* Hillary Clinton. Such properties are sometimes called *extrinsic* or *relational properties*. Objects have them because of their relations to other things. By contrast, *intrinsic* or *non-relational properties* are properties that a thing has quite independently of its relationships to other things. Many properties that seem to be intrinsic turn out to be extrinsic when we examine them carefully. The main questions here are whether there are any interesting intrinsic properties and how the notions of intrinsicness and extrinsicness are to be explicated.

Primary vs. Secondary Properties

The distinction between primary and secondary properties goes back to the Greek atomists. It lay dormant for centuries, but was revived by Galileo, Descartes, Boyle, Locke, and others during the seventeenth century. Locke's influence is so pervasive that such properties still often go under the names he gave them, *primary* and *secondary qualities*.

The intuitive idea is that primary properties are objective features of the world; on many accounts they are also fundamental properties that explain why things have the other properties that they do. Early lists of primary properties included *shape*, *size*, and (once Newton's influence was absorbed) *mass*. Today we might add properties like *charge*, *spin* or the *four-vectors* of special relativity to the list of primary properties. By contrast, secondary properties somehow depend on the mind; standard lists of secondary properties include *colors*, *tastes*, *sounds*, and *smells*. On Locke's account secondary properties are powers of objects that are rooted in the primary properties. The most pressing question about the two kinds of properties is how (if at all) a precise and informative distinction can be drawn between them. Issues involving primary and secondary properties have been revived in the recent flurry of discussions of color.

Supervenient Properties

Supervenience is sometimes taken to be a relationship between two fragments of language (e.g., between psychological vocabulary and physical vocabulary), but it is increasingly taken to be a relationship between pairs of *families of properties*. To say that psychological properties supervene on physical properties, for example, is to say that, necessarily, everything that has any psychological properties also has physical properties and any two things that have exactly the same physical properties will have exactly the same psychological properties. There are no differences in psychological properties without some difference in physical properties.

There is no consensus as to how globally to construe supervenience claims. In the case of psychological and physical properties it seems too narrow to say that the non-relational psychological properties of a person supervene on her non-relational physical properties (too many important psychological properties involve relationships to things outside the organism for this to be right). And it seems unhelpfully narrow just to say that any two worlds that are just alike in their distributions of physical properties will be just alike in their distributions of psychological properties. But however we phrase the doctrine (and no doubt different versions will be useful for different purposes), supervenience is very naturally construed as a relation between pairs of families of properties.

In some cases it also seems plausible to think of the supervenient realm as linguistic and the supporting, subvenient realm in terms of properties: there can be no difference in truths in the upper realm (e.g., those employing psychological vocabulary) without a difference in properties (e.g., physical properties) at the lower level. But this hybrid approach has not received much attention.

Fictional Properties

We might arrive at a notion of *fictional properties* in the following way. In *Naming and Necessity* Kripke discusses what he calls ‘mythical species’ (1980, pp. 156-158). On Kripke's view, ‘Sherlock Holmes’ does not denote anyone, neither an actual individual or a merely possible one. The name fails to denote because all our descriptions of Holmes are essentially incomplete. They do not fully specify a unique person (not even a unique merely possible person), and so there are many different possible detectives who have all of the properties ascribed to Holmes but who differ in other ways. No one of them has any more claim on being Holmes than any of the rest, and so there are no counterfactual situations that could correctly be described as ones in which Holmes exists.

The properties ascribed to unicorns are similarly incomplete. There are many different possible species that have the properties we commonly ascribe to unicorns but which differ in other ways. No one of these species has any more claim on being unicorns than any of the rest, and so there are no counterfactual situations that could correctly be described as ones in which unicorns exists. It may also be the case, though Kripke doesn't discuss the matter, that notions like phlogiston and caloric fluid are similarly incomplete, and that there are no counterfactual situations that could correctly be described as ones in which anything has the property of *being phlogiston* or that of *being caloric fluid*. But even if this further claim isn't true, Kripke's example of unicorns suggests that there may be a distinction between actual properties and fictional properties. There are interesting philosophical issues about fictional characters, individuals like Holmes and Pegasus and the bride of Frankenstein, and there may be similarly interesting questions about fictional properties. Aside from Zalta (1983), however, little work has been done on this topic.

8 Formal Theories of Properties

In this section I will explain some of the most rudimentary ideas behind several recent formal theories of properties. The aim is to convey the intuitive flavor of this work, so I will proceed primarily by example

rather than with definitions and proofs (interested readers can find plenty of both in the works cited below).

There are several important choices that must be made in devising a formal theory of properties; they include the following:

1. Should the account be developed as a formal theory in a familiar logic (in the way set theories are now standardly axiomatized in standard first-order logic)? This was the approach in the early formal theories of Barcan-Marcus (1963) and Lemmon (1963), who used first-order modal logic (see Jubien, 1989, for a recent, more sophisticated (and non-modal) implementation of this approach). Alternatively, should a formal account of properties be developed as a richer "logic of properties" (e.g., Bealer, 1982; Zalta, 1983; Menzel, 1993; Swoyer, 1998)?
2. Should we employ a typed or an untyped conception of properties (the latter is much more flexible, but it must be handled with care to avoid paradox)?
3. Should we make provisions for complex predicates (or complex singular terms, or both) with something akin to a logical structure?
4. Should we require all of the expressions in the syntactic categories that can denote (or express) properties to do so or should we allow some or all of them not to?

Different choices are recommended by different conceptions of properties. For the sake of exposition I will begin with those choices that minimize the departures from familiar logical systems like non-modal first-order logic. This means a logic of properties that is typed, that does not include complex properties, and in which every predicate expresses a property. We will then see how to extend this approach in various ways.

8.1 A Bare-Bones Logic of Properties

Think of your favorite formulation of first-order logic with identity. Then just add *n*-place predicate variables (for all positive integers *n*) to its syntax and count any *n*-place predicate variable followed by *n* individual terms (i.e., by individual variables and constants) as a formula. Finally, allow *n*-place predicate variables to be bound by quantifiers containing an *n*-place predicate variable (in just the same way that individual variables can be), and count formulas with no free variables as sentences. For example, the expression ‘X^3abc’ is a formula consisting of the three-place predicate variable ‘X^3’ followed by the three individual terms ‘*a*’, ‘*b*’, and ‘*c*’; since the predicate variable is unbound, this formula is not a sentence. By contrast, ‘$(\exists X^2)X^2ab$’ is a sentence (here ‘$\exists$’ is the existential quantifier; this sentence says that there is at least one two-place relation that relates *a* to *b* or, more idiomatically, that *a* stands in some binary relation to *b*).

We interpret languages in this logical system over *Intensional Relational Structures* (*IRS*s). An *IRS* is an ordered triple:

$$\mathbf{I} = \langle \mathbf{D_I}, \mathbf{D_P}, \mathbf{ext} \rangle,$$

where $\mathbf{D_I}$ and $\mathbf{D_P}$ are non-empty, non-overlapping sets. On intended interpretations (which we will take for granted here) $\mathbf{D_I}$ is the domain of individuals and $\mathbf{D_P}$ is the domain of properties (including relations). $\mathbf{D_P}$ is in turn the union of an infinite number of non-overlapping, non-empty sets: ${}^1\mathbf{D_P}$ (the set of one-place properties), ${}^2\mathbf{D_P}$ (the set of two-place relations), ${}^3\mathbf{D_P}$ (the set of three-place relations), and so on for each positive integer *n*. Finally, **ext** is an extension assignment function; it assigns an extension to every property in the property domain $\mathbf{D_P}$ in accordance with the following rule:

> Where $\mathbf{P}^n$ is an *n*-place property, **ext** assigns $\mathbf{P}^n$ a (possibly empty) set of ordered *n*-tuples whose members are drawn from the individual domain $\mathbf{D_I}$

(we take an ordered one-tuple whose member is *a* to be *a* itself). Hence, the extension assignment assigns each one-place property a subset of the individual domain, each two-place property (i.e., each binary relation) a set of ordered pairs on individuals, and so on. In other words, it assigns exactly the same sorts of extensions to *n*-place properties that interpretations in standard first-order logic assign to *n*-place predicates.

Finally, a *model* or *interpretation* on an *IRS* interprets our formal language over it. It assigns a denotation to each individual constant (exactly as in standard first-order logic) and an *n*-place property to each *n*-place predicate (here we go beyond standard first-order logic). The fundamental idea is just that:

- An atomic sentence like 'F^1a', is *true in the model* just in case the object denoted by '*a*' is in the extension of the property denoted by 'F^1',
- An atomic sentence like 'F^2ab', is *true in the model* just in case the ordered pair containing the objects denoted by '*a*' and '*b*' (in that order) is in the extension of the (two-place) property denoted by 'F^2',
- ...and so on.[1]

As in first-order logic, we must add variable assignments (or their equivalents) to explain the workings of quantifiers. A variable assignment assigns an object of the appropriate sort to each variable of the language (it assigns individuals to individual variables, one-place properties to one-place predicate variables, two-place properties (binary relations) to two-place predicate variables, and so on). We then define satisfaction conditions for formulas (in a model and relative to a variable assignment) just as we do in standard first-order logic. Finally, a formula is true in a model just in case it contains no unbound variables and is satisfied by every variable assignment with respect to the model; a sentence is valid if is true in all models; and a set of sentences entails a sentence if that sentence is true in every model in which all of the sentences in the set are true. It is routine to extend such logics to higher orders, so that first-level properties can have second-level properties and stand in second-order relations, and so on up.

Untyped Variants

Philosophers, linguists, and computer scientists have increasingly chafed under the inflexible aspects of typed theories, and several recent accounts treat properties as individuals that are included in the range of the quantifiers for ordinary individuals. One way to accommodate this approach is to modify *IRS*s so that they include just a single domain that contains both properties and individuals. We then introduce *n*-place property-designating singular terms and require that an interpretation assign them denotations of the appropriate sort. For example, a one-place term of this sort might be used to represent the word ‘honesty’, and a three-place term of this sort might be used to represent ‘betweeness’. We can still allow predicates to denote properties (or we can introduce a new semantic relation, *expression*, which assigns properties to predicates). This allows something akin to self predication; if ‘*F*’ denotes (or expresses) the same property that the one-place singular term ‘*a*’ denotes, then ‘*Fa*’ will be true just in case the property denoted by ‘*a*’ is in the extension of itself. Quite intricate variations on this basic theme are possible; the most detailed is Bealer's (1982) first-order intensional logic that includes intensional abstracts among its singular terms.

Complex Terms and "Compound" Properties

It is much easier to deal with some features of natural language if we include complex predicates in our language and introduce a systematic way of interpreting them over *IRS*s. In the 1970s it occurred to several people that a rigorous formal system embodying this conception of properties could be constructed by investing the operations on linguistic expression in systems like Quine's predicate functor logic (1960) with an extra-linguistic, ontological status (e.g., Bealer, 1973, 1982; McMichael & Zalta, 1981; Leeds, 1978). Adding the machinery necessary to accommodate all of the complex predicates we might want is quite intricate (see Zalta, 1983 for a very readable account), and here I will just mention two examples to convey the general idea.

The first step is to introduce a variable-binding operator, λ, that allows us to construct complex predicates from open formulas. For example, we can apply ‘λ’ to the open formula, ‘*Rx* & *Sx*’ to form the one-place complex predicate ‘[λx (*Rx* & *Sx*)]’; if ‘*R*’ denotes *being red* and ‘*S*’ denotes *being square*, then this complex predicate denotes the compound, conjunctive property *being red and square* (a stilted, but sometimes useful rendering of this is ‘the property of being a thing that is both red and square’). Similarly, we can apply the operator to the open formula ‘∃*y*(*Lxy*)’ to form the one-place predicate ‘[λx ∃*y*(*Lxy*)]’; if ‘*L*’ stands for *loves*, this complex predicate denotes the compound property *loving someone* (whereas ‘[λy ∃*x*(*Lxy*)]’ would denote *being loved by someone*).[2]

Although the guiding ideas here are relatively straightforward, considerable delicacy is required to ensure that everything works out in precisely the right way. For example, an object should exemplify the conjunctive property denoted by ‘[λx (*Rx* & *Sx*)]’ if and only if it exemplifies both the properties *R* and *S*. And an object should exemplify the property denoted by ‘[λy ∃*x*(*Lxy*]’ just in case it loves some object (and just in case it does *not* exemplify the property denoted by ‘[λy ~∃*x*(*Lxy*]’). There are many systematic connections of this sort among complex predicates, compound properties, and the things that exemplify them, and some fairly heavy machinery is required to ensure that things work smoothly for properties of arbitrarily complexity. (Consider, for example, [λxyz ∃*w*(*Fxyw* & ~(*Gy* or ∃*v*(*Hzvy*)))].)

One way to make all of this work as it should is to add operations to *IRS*s that allow us to "build" compound properties up out of simpler ones. For example, to accommodate conjunctive properties we introduce an operation, **&**, that maps each pair of properties, **P** and **Q** (having the same number of argument places, though this restriction can be dropped at a slight cost of simplicity) to the conjunctive property **P & Q**. To ensure that things work properly we must *also* add a clause specifying how the **&**-operation interacts with the extension assignment function. In particular, we require that **ext**(**P & Q**) be the intersection of **ext**(**P**) and **ext**(**Q**).

By adding a handful of additional "property-building" operations (corresponding to the various connectives, quantifiers, operations on relations like conversion, and the syntactic operation of substitution), clauses specifying how each operation interlocks with the extension assignment, and a recursive definition of the denotations of predicates, we can ensure that complex predicates denote properties that behave as they should (Zalta, 1983 contains an elegant account of one way to do this; Swoyer, 1998 contains a slightly different approach in which assignments of denotations to complex predicates and assignments of extensions to the properties they denote are both treated as homomorphisms). With such a rich stock of properties we can add a comprehension schema to our logic which tells us that each condition (open formula) determines a property, i.e., there is at least one property that an ordered group of things has just in case the open formula is true of them.[3] It is also possible to add complex singular terms to the language; these are formal counterparts of nominalizations like *being poor but happy*. We can then set up the semantics so that these abstract singular terms denote compound properties.

Logic and the Empirical Conception of Properties

Some realists hold that it is an empirical question just which properties there are. On this view, there can be no logical or a priori existence conditions for properties. It is possible to formulate a very minimal logic (Swoyer, 1993; 1998) that fits nicely with this conception. Because it is so minimal, it has a philosophical neutrality that provides a framework in which various richer theories of properties (including ones with complex predicates) can be formulated, classified, and compared.

The Status of Formal Theories

There are two ways to view the kinds of formal systems described in this section (whether we call them ‘logics’ or not). We can view them as attempts to tell the One True Story about an abstract realm of properties (or the One True Story about the logical structure underlying a natural language like English or Hindi). On this construal the various systems are competitors. But it is also possible to view such formal systems in a more prosaic way, as abstract models that allow us to represent and reason about various phenomena involving properties (including various fragments of English). On this picture, such systems are similar in important respects to formal models in the sciences. They always involve simplifications and idealizations, and different models are useful for different purposes. Moreover, if a simpler model is enough to handle the phenomenon we are interested, it is overkill to employ more complex models even if they are available.

Future Directions

Various combinations of the features discussed in this section are possible. At this point several extensions also seem desirable, including allowing multigrade predicates like ‘had a knock-down, drag-out fight with each other’ and multigrade properties. It is also important to extend current accounts to deal with vagueness, and it would be gratifying to see them make contact with recent empirical work on concepts and categorization.

8.2 The Mereology of the Forms?

There has been some discussion of complex or structural properties in the recent literature, and certainly the metaphor of relation-building operations (like **&**) may suggest that some properties literally have parts. This idea can be traced back to Plato's later dialogues, where he speaks of one Form being part of another (*Sophist*, 257d). It has been defended recently by Armstrong (1978, pp. 36-39, pp. 67f) and Bigelow and Pargetter (1989). This view may have some plausibility for certain sorts of properties, e.g., conjunctive properties. But the general view (which these philosophers do not endorse) that properties literally have logical structures that mirror the syntactic structures of the complex predicates that denote them is less appealing. In the case of a negative property, for example, it would require us to think that the property *F* is somehow part of the negative property, *being a non-F*.

Structured Specifications vs. Specifications of Structure

On an alternative view, the appearance that some properties are literally structured is an artifact of our use of structured terms (complex, λ-predicates like ‘[λ*x* (*Rx* & *Sx*)]’) to denote them. But our use of structured terms and structural metaphors doesn't mean that the properties themselves are genuinely structured or that they literally have parts. There is a difference between *structured specifications*, which we do employ, and *specifications of structure*, which is another matter entirely. There *are* logical relations among properties; *being F* and *being not F* are inconsistent (in the sense that nothing could exemplify both at once); *being F and G* entails *being F* (in the sense that anything exemplifying the former property must also exemplify the latter). These logical relations do structure the realm of properties. This makes a structured specification a natural device for singling out a member of this structured realm of entities, since it identifies it by its place--its logical location--in that domain. But the role of the syntactic structure of a complex predicate is not to exhibit the internal structure of a property; it is to disclose that property's niche in the logical network of properties. We should add the cautionary note that a picture of compound properties needn't be a package deal. It is possible to argue that there are no compound properties, that there are some but not others (e.g., there might be conjunctive, but no disjunctive, properties), or that there is a multitude of them. Which view is correct? That is a philosophical question, and formal work alone cannot answer it.

Uses of Properties in the Philosophy of Mathematics

1. Logicist Identificationism

The first detailed version of identificationism was developed by Gottlob Frege, in which numbers were identified with sets. (Frege actually identified numbers with the extensions of second-order concepts, but since these are extensional creatures, it isn't wildly anachronistic to think of them as sets. See the entry on Frege's logic, theorem and foundations for arithmentic.) But Frege made a further claim: these extensions, and hence the numbers, are *logical* entities, ones whose very existence is guaranteed by logic alone. Hence, truths of number theory are really just logical truths. This thesis, which came to be known as *logicism*, offered the hope of an extremely secure foundation for arithmetic that fulfilled wishes 4 (telling us how arithmetical truths can be necessarily true) and 5 (telling us how we have *a priori* knowledge in mathematics). After all, logical truths are surely necessarily true if anything is, and if anything can be known *a priori*, they surely can be. Indeed, they are usually thought to be analytic, and there is supposed to be little puzzle about how we can know such truths *a priori*; we just analyze the meanings of terms.

In their monumental, three-volume work *Principia Mathematica*, Whitehead and Russell develop logicism in a slightly different way. They identify numbers with propositional functions which, owing to unclarity of exposition, hover between properties, on the one hand, and linguistic expressions (open sentences, predicates roughly), on the other. But they quantify over propositional functions in a way that treats them as properties, so this early version of logicism actually identifies numbers with properties rather than with sets. Whitehead and Russell don't make use of the intensionality of properties, however, and they could as well have used sets. More recently several philosophers, particularly Bealer (1982, ch 5-6; cf. Menzel, 1986) have argued that logic alone guarantees the existence of enough properties with the right structure to play the role of the natural numbers. This requires a conception of logic much richer than many traditional ones; among other things, logic alone must ensure the existence of infinitely many things (such systems, which are quite intricate, are beyond the scope of the present article, but a few of the basic ideas are explained in §8).

Champions of a logicism based on properties can simply adapt earlier identificationist's explanations of truth, objectivity, and logical form, substituting properties for the sets employed in the earlier accounts. Moreover, they can hold that the existence of properties, at least those identified with the numbers, is guaranteed by logic. And since logical truths are necessarily true, these properties necessarily exist and they necessarily stand in the (mathematically relevant) relations that they do, which explains the modal

status of arithmetic claims. None of this tells us how mathematical knowledge is possible; any account of this will require substantive auxiliary hypotheses about human cognitive faculties.

This brief account of property-theoretic versions of logicism can't do justice to their details, but it tells us enough to spot several likely objections to them. They face problems peculiar to logicism as well as more general problems that threaten most versions of identificationism.

2. Set-theoretic Identificationism

These steps are familiar from set-theoretic versions of identificationism in which numbers are identified with sets. For example, we might identify zero with the empty set, Ø, and for each x in the domain, the successor of x, $s(x)$, could be identified with $\{x\}$ (as in Zermelo's account), or with the union of x and $\{x\}$ (as in von Neumann's account), or with the result of applying some other operation of the appropriate sort to x (when there is one way to do this, there are lots of ways). Classical versions of identificationism begin with a formal theory of the objects we take to be numbers, and the task is to show that arithmetical truths match up with truths of this theory and that arithmetical falsehoods match up with its falsehoods. When the proposed identification is with sets, this involves deriving the set-theoretic translations of our favorite set of axioms for number theory in some version of set theory.

3. Logicism and Logic

The exact character of logic is elusive; indeed, there is some reason to think that, like many other notions, it is vague around the edges. But one traditional hallmark of logic is that it is topic neutral; it applies to everything indifferently; it doesn't deal explicitly with specific sorts of things like planets or dogs or the number 16. The notion of a property is very general, however, since it is plausible to suppose that absolutely anything can exemplify a property, so there is some room to argue that logic can guarantee the existence of properties without violating its topic-neutrality.

A second traditional hallmark of logic is that it does not make existence commitments, at least not any specific ones. It is true that theorems of our most familiar logical system, first-order logic, are only true in circumstances in which at least one thing exists. But this one thing can be *any* sort of thing at all, and this system is sometimes criticized for assuming even this much (this is one reason why some philosophers prefer free logic, which doesn't make even this minimal commitment). In the end, though, it is less important to decide whether rich and powerful systems count as logic than to see whether they have the sorts of features that make logicism attractive in the first place.

It may seem plausible to view theorems of classical sentential logic as analytic, true in virtue of the

meanings of the logical constants they contain. But it is generally agreed that existence claims are not analytic (this is the root of the problem with the ontological argument). So the nice, intuitive view that mathematical knowledge is no great mystery (it's simply knowledge of analytic logical truths) seems less plausible once the notion of logic is stretched to become so powerful. Moreover, this stretching doesn't end with the requirement that our logic of properties guarantee the existence of infinitely many things. First-order logic is not strong enough to characterize the natural numbers even up to isomorphism, and logics that are do not have recursively enumerable sets of logical truths (by Gödel's theorem). Hence, such systems are epistemically untractable in the sense that their truths far outrun our ability to track (prove) them.

In short, it may well be a merely verbal dispute just which formal systems merit the honorific title of ‘logic’. The substantive point here is that if logicism requires a logic that is so lavish in its existence commitments and so computationally (and hence epistemologically) unruly, then the appeal that the slogan "truths of arithmetic are just truths of logic" had when we had a kinder and gentler vision of logic in mind begins to fade. Indeed, as we will now see, logicist identificationism does not turn out to be so very terribly different from its non-logicist counterparts.

4. Non-logicist identificationism

In view of the heavy existence commitments of number theory, most philosophers came to doubt that "reductions" of arithmetic to set theory really counted as reductions to logic (and parallel reasoning would lead them to doubt that using a logic of properties rather than set theory changes this). Instead, the reducing theory, that of sets, came to be seen as an independent formal theory with its own proprietary existence commitments that was best formulated in, but was not identical with, some logical system (as the decades rolled by this system was increasingly first-order logic).

The claim that numbers are identical with sets is really all we need to mobilize the logicist's accounts of mathematical truth, objectivity, and logical form. Furthermore, since the sets identified with numbers are all pure sets (they don't have any members that aren't themselves sets), it can be argued that they exist necessarily, which explains the modal status of mathematical claims. The important point here is that a property theorist can write a set of axioms for property theory that parallel the axioms of standard set theories (save for replacing the axiom of extensionality with some other identity condition, perhaps omitting the axiom of foundations, and making other minor emendations to adapt the ideas better to properties; e.g., Jubien, 1989; cf. Pollard and Martin, 1986). The resulting axioms are not viewed as part of logic, but as a characterization of an independently existing realm of properties. And once this is done, the property theorist can adapt the explanations given by those non-logicists who identify numbers with sets to explain all of the items on our list except for the one involving mathematical knowledge.

Gottlob Frege

Gottlob Frege (b. 1848, d. 1925) was a German mathematician, logician, and philosopher who worked at the University of Jena. Frege essentially recreated the discipline of logic by constructing the first ‘predicate calculus’. In this calculus, Frege developed a new analysis of atomic and quantified statements and formalized the notion of a ‘proof’ in terms that are still accepted today. Frege then demonstrated that one could use this calculus to resolve theoretical mathematical statements in terms of simpler logical and mathematical notions. One of the axioms that Frege later adopted for his system, in the attempt to derive significant parts of mathematics from logic, proved to be inconsistent. Nevertheless, his definitions (of the *predecessor* relation and of the concept of *natural number*) and methods (for deriving the axioms of number theory) were insightful and constituted a significant advance. To ground his views about the relationship of logic and mathematics, Frege conceived a comprehensive philosophy of language that many philosophers still find insightful. However, his lifelong project, of showing that mathematics was reducible to logic, was not successful.

Frege's Life

- 1848, born November 8 in Wismar (Mecklenburg-Schwerin)

- 1869, entered the University of Jena
- 1871, entered the University of Göttingen
- 1873, awarded Ph. D. in Mathematics (Geometry), University of Göttingen
- 1874, earned a Habilitation in Mathematics, University of Jena
- 1874, became Privatdozent, University of Jena
- 1879, became Professor Extraordinarius, University of Jena
- 1896, became ordentlicher Honorarprofessor, University of Jena
- 1917, retired from the University of Jena
- 1925, died July 26 in Bad Kleinen (now in Mecklenburg-Vorpommern)

Frege's Advances in Logic

Frege virtually founded the modern discipline of mathematical logic. He forever changed the way philosophers and mathematical logicians think about the predicate calculus, the analysis of simple sentences and quantifier phrases, proofs, the foundations of mathematics, definitions, and the ‘natural numbers’.

The Predicate Calculus

In an attempt to realize Leibniz's ideas for a language of thought and a rational calculus, Frege developed a formal notation for regimenting thought and reasoning (see his *Begriffsschrift*). Though we no longer use his notation, Frege's in effect developed the first predicate calculus. A predicate calculus is a formal system with two components: a formal language and a logic. The formal language Frege designed was capable of: (a) expressing predicational statements of the form ‘*x* falls under the concept *F*’ and ‘*x* bears relation *R* to *y*’, etc., (b) expressing complex statements such as ‘it is not the case that ...’ and ‘if ... then ...’, and (c) expressing ‘quantified’ statements of the form ‘Some *x* is such that ...*x*...’ and ‘Every *x* is such that ...*x*...’. The logic of Frege's calculus was a set of rules that govern when some statements of the language may be correctly inferred from others.

Frege's system was powerful enough to resolve the essential logic of mathematical reasoning. That was partly due to the fact that his predicate calculus was a ‘second-order’ predicate calculus, allowing statements of the form ‘Some concept *F* is such that ...*F*...’ and ‘Every concept *F* is such that ...*F*...’. However, the most important insight underlying Frege's calculus was his ‘function-argument’ analysis of sentences. This freed him from the limitations of the ‘subject-predicate’ analysis of sentences that formed the basis of Aristotelian logic and it made it possible for him him to develop a general treatment of quantification.

The Analysis of Atomic Sentences and Quantifier Phrases

In traditional Aristotelian logic, the subject of a sentence and the direct object of a verb are not on a logical par. The rules governing the inferences between statements with different but related subject

terms are different from the rules governing the inferences between statements with different but related verb complements. For example, in Aristotelian logic, the rule which permits the valid inference from ‘John loves Mary’ to ‘Something loves Mary’ is different from the rule which permits the valid inference from ‘John loves Mary’ to ‘John loves something’. The rule governing the first inference is a rule which applies only to the subject terms ‘John’ and ‘Something’. The rule governing the second inference applies only to the transitive verb complements ‘Mary’ and ‘something’. In Aristotelian logic, these inferences have nothing in common.

In Frege's logic, a single rule governs both the inference from ‘John loves Mary’ to ‘Something loves Mary’ and the inference from ‘John loves Mary’ to ‘John loves something’. This was made possible by Frege's analysis of atomic and quantified sentences. Frege took intransitive verb phrases such as ‘is happy’ to be functions of one variable (‘*x* is happy’), and resolved the sentence "John is happy" in terms of the application of the function denoted by ‘is happy’ to the argument denoted by ‘John’. In addition, Frege took the verb phrase ‘loves’ to be a function of two variables (‘*x* loves *y*’) and resolved the sentence ‘John loves Mary’ as the application of the function denoted by ‘*x* loves *y*’ to the objects denoted by ‘John’ and ‘Mary’ respectively. In effect, Frege saw no distinction between the subject ‘John’ and the direct object ‘Mary’. What is logically important is that ‘loves’ denotes a function of 2 arguments, that ‘gives’ denotes a function of 3 arguments (*x* gives *y* to *z*), that ‘bought’ denotes a function of 4 arguments (*x* bought *y* from *z* for amount *u*), etc.

This analysis allowed Frege to develop a more systematic treatment of quantification than that offered by Aristotelian logic. No matter whether the quantified expression ‘something’ appears within a subject ("Something loves Mary") or within a predicate ("John loves something"), it is to be resolved in the same way. In effect, Frege treated quantified expressions as variable-binding operators. The variable-binding operator ‘some *x* is such that’ can bind the variable ‘*x*’ in the expression ‘*x* loves Mary’ as well as the variable ‘*x*’ in the expression ‘John loves *x*’. Thus, Frege analyzed the above inferences in the following general way:

- John loves Mary. Therefore, some *x* is such that *x* loves Mary.
- John loves Mary. Therefore, some *x* is such that John loves *x*.

Both inferences are instances of a single valid inference rule.

Proof

As part of his predicate calculus, Frege developed a strict definition of a ‘proof’. In essence, he defined a proof to be any finite sequence of well-formed statements such that each statement in the sequence either is an axiom or follows from previous members by a valid rule of inference. A proof of the statement B from the premises $A_1,...,A_n$ is any finite sequence of statements (with B the final statement in the sequence) such that each member of the sequence: (a) is one of the premises $A_1,...,A_n$, or (b) is an axiom, or (c) follows from previous members of the sequence by a rule of inference. This is essentially the definition of a proof that logicians still use today.

Definition

Frege was extremely careful about the proper description and definition of logical and mathematical concepts. He developed powerful and insightful criticisms of mathematical work which did not meet his standards for clarity. For example, he criticized mathematicians who defined a variable to be a number that varies rather than an expression of language which can vary as to which determinate number it refers to. And he criticized those mathematicians who developed ‘piecemeal’ definitions or ‘creative’ definitions. In the *Grundgesetze* (Band II, Sections 56-67) Frege criticized the practice of defining a concept on a given range of objects and later redefining the concept on a wider, more inclusive range of concepts. Frequently, this ‘piecemeal’ style of definition led to conflict, since the redefined concept did not always reduce to the original concept when one restricts the range to the original class of objects. In that same work (Band II, Sections 139-147), Frege criticized the mathematical practise of introducing notation to name (unique) entities without first proving that there exist (unique) such entities. He pointed out that such ‘creative definitions’ were simply unjustified.

A Foundation for Mathematics

Frege attempted to construct a foundation for mathematics. His most comprehensive logical system was developed in his landmark work *Grundgesetze der Arithmetik*, in which he attempted to validate the philosophical doctrine known as *logicism*, i.e., the idea that mathematical concepts can be defined in terms of purely logical concepts and that mathematical axioms can be derived from the laws of logic alone. Unfortunately, Frege employed a principle in the *Grundgesetze* (Basic Law V) which turned out to be subject to Russell's Paradox. This paradox caused him to question the truth of logicism, and few philosophers today believe that mathematics can be reduced to logic. Mathematics seems to require some non-logical notions (such set membership) and some non-logical axioms (such as the non-logical axioms of set theory). Despite the fact that a contradiction invalidated a part of his system, the intricate theoretical web of definitions and proofs developed in the *Grundgesetze* produced a conceptual framework for mathematical logic that was nothing short of revolutionary. There is no doubt that the logical system and maze of definitions developed by Bertrand Russell and Alfred North Whitehead in *Principia Mathematica* owe a huge debt to the work found in Frege's *Grundgesetze*.

The Natural Numbers

In his seminal work *Die Grundlagen der Arithmetik*, Frege successfully defined the notion of a ‘cardinal number’ in terms of the primitive notion of an *extension* or *set*. The insight behind the definition is that a statement of cardinal number such as ‘There are *n* *F*-things’ predicates a higher-order concept of the concept *F*, namely, that it is a concept under which *n* things fall. Frege simply defines the (cardinal) number of the concept *F* (i.e., the number of *F*s) as the extension of the concept *being a concept equinumerous to F*. On this definition, the number of planets is identified as the extension of the concept *being a concept equinumerous to the concept of being a planet*. In other words, the number of planets is

an extension (or set) which contains all those concepts which, like the concept *being a planet*, are exemplified by nine objects.

Frege defined the concept of *natural number* by defining, for every relation *xRy*, the general concept '*x* is an ancestor of *y* in the R-series' (this new relation is called 'the ancestral of the relation R'). The ancestral of a relation R was first defined in Frege's *Begriffsschrift*. The intuitive idea is easily grasped if we consider the relation *x* is the father of *y*. Suppose that *a* is the father of *b*, that *b* is the father of *c*, and that *c* is the father of *d*. Then Frege's definition of '*x* is an ancestor of *y* in the fatherhood-series' ensured that *a* is an ancestor of *b*, *c*, and *d*, that *b* is an ancestor of *c* and *d*, and that *c* is an ancestor of *d*.

More generally, if given a series of facts of the form *aRb*, *bRc*, *cRd*, and so on, Frege showed how to define the relation *x is an ancestor of y in the R-series* (this is the ancestral of the relation R). To exploit this definition in the case of natural numbers, Frege had to define both the relation *x precedes y* and the ancestral of this relation, namely, *x is an ancestor of y in the predecessor-series*. He first defined the relational concept *x precedes y* as follows:

> *x precedes y* iff there is a concept *F* and an object *z* such that:
>
> - *z* falls under *F*,
> - *y* is the (cardinal) number of the concept *F*, and
> - *x* is the (cardinal) number of the concept *object other than z falling under F*

In the notation of the second-order predicate calculus, Frege's definition becomes:

$$Precedes(x,y) \quad =_{df} \quad \exists F \exists z (Fz \;\&\; y = \#F \;\&\; x = \#[\lambda u \; Fu \;\&\; u \neq z])$$

To see the intuitive idea behind this definition, consider how the definition is satisfied in the case of the number 1 preceding the number 2: there is a concept *F* (e.g., let *F*=the concept *being an author of Principia Mathematica*) and an object *z* (e.g. let *z*=Alfred North Whitehead) such that:

- Whitehead falls under the concept *being an author of Principia Mathematica*,
- *2* is the (cardinal) number of the concept *being an author of Principia Mathematica*, and
- *1* is the (cardinal) number of the concept *object other than Whitehead which falls under the concept being an author of Principia Mathematica*

Note that the last conjunct is true because there is exactly 1 object (namely, Bertrand Russell) which falls under the concept *object other than Whitehead which falls under the concept being an author of Principia Mathematica*.

Given this definition of *precedes,* Frege then defined the ancestral of this relation, namely, *x is an ancestor of y in the predecessor-series*. So, for example, if 10 precedes 11 and 11 precedes 12, it follows that 10 is an ancestor of 12 in the predecessor-series. Note, however, that although 10 is an ancestor of

12, 10 does not precede 12, for the notion of *precedes* is that of *strictly* precedes. Note also that by defining the ancestral of the precedence relation, Frege had in effect defined $x < y$.

Frege then defined the number 0 as the (cardinal) number of the concept *being an object not identical with itself*. The idea here is that nothing fails to be self-identical, so nothing falls under this concept. The number 0 is therefore identified with the extension of all concepts which fail to be exemplified.

Finally, Frege defined:

> *x is a natural number* iff either x=0 or 0 is an ancestor of x in the predecessor series

In other words, a natural number is any member of the predecessor series beginning with 0.

Using this definition, Frege derived many important theorems of number theory. It was recently shown by R. Heck [1993] that, despite the logical inconsistency in the system of his *Grundgesetze*, Frege validly derived the Dedekind/Peano Axioms for number theory from a powerful and consistent principle now known as Hume's Principle ("The number of Fs is equal to the number of Gs if and only if there is a one-to-one correspondence between the Fs and the Gs"). Although Frege used his inconsistent axiom Basic Law V to establish Hume's Principle, once Hume's Principle was established, Frege validly derived the Dedekind/Peano axioms without making any further essential appeals to Basic Law V. Following the lead of George Boolos, philosophers today call derivation of the Dedekind/Peano Axioms from Hume's Principle ‘Frege's Theorem’. The proof of Frege's Theorem was a *tour de force* which involved some of the most beautiful, subtle, and complex logical reasoning that had ever been devised. For a comprehensive introduction to the logic of Frege's Theorem, see the entry Frege's logic, theorem, and foundations for arithmetic.

Frege's Ontology and Philosophy of Language

While pursuing his investigations into mathematics and logic (and quite possibly, in order to ground those investigations), Frege was led to develop not only an ontology of *functions* and *objects* but also a philosophy of language. In his ontology, Frege asserted the existence of two special objects, namely, the truth values The True and The False and defined *concepts* as a special kind of function, namely, any function that mapped objects to truth values. He also suggested that *existence* is not a property of objects but rather of concepts. Frege is most well-known among philosophers, however, for the way these ideas were applied and extended in his philosophy of language. His seminal paper in this field ‘Über Sinn und Bedeutung’ (‘On Sense and Denotation’) is now a classic. In this paper, Frege considered two puzzles about language and noticed, in each case, that one cannot account for the meaningfulness or logical behavior of certain sentences simply on the basis of the denotations of the terms (names and descriptions) in the sentence. One puzzle concerned identity statements and the other concerned sentences with relative clauses such as propositional attitude reports. To solve these puzzles, Frege suggested that the terms of a language have both a sense and a denotation (i.e., that at least two semantic relations are

required to explain the significance or meaning of the terms of a language). This idea has inspired research in the field for over a century.

Frege's Ontology

In Frege's ontology, functions and objects were rigorously distinguished as two fundamentally different kinds of entity. Functions are the kind of thing that take objects as arguments and map those arguments to a value. Frege did not limit examples of functions to mathematical functions such as $x + 3$. He allowed the variable x to range over any object, and so *father of x* is a genuine example of a function---it maps certain biological offspring to their fathers and maps everything else to The False. Frege associates with every function, a *course-of-values*. The course-of-values of a function explicitly indicates the value of the function for each object that is supplied as an argument. In addition, Frege believed that there are two distinguished objects, namely, the truth value The True and the truth-value The False. Those functions which map objects to truth values are called *concepts*. For example, not only is the mathematical function $x + 3=5$ a concept (this concept maps the number 2 to The True and everything else to The False), but so is the function *x is happy* (which maps anything that is happy to The True and everything else to The False). Frege defines the *extension* of a concept to contain just those objects which the concept maps to The True (as indicated by the course-of-values associated with the concept).

Frege suggested that *existence* is not a property of objects but rather of concepts: it is the property a concept has just in case it has an non-empty extension (i.e., just in case it maps some object to The True). So the fact that the extension of the concept *martian* is empty underlies the ordinary claim "Martians don't exist." Frege therefore took *existence* to be a ‘second-level’ concept.

Frege's Puzzles

Frege's Puzzle About Identity Statements. Here are some examples of identity statements:

> 117 + 136=253.
> The morning star is identical to the evening star.
> Mark Twain is Samuel Clemens.
> Bill is Debbie's father.

Frege believed that these statements all have the form "$a=b$", where ‘*a* ’ and ‘*b* ’ are either names or descriptions that *denote* individuals. He naturally assumed that a sentence of the form "$a=b$" is true if and only if the object denoted by ‘*a* ’ is the same as the object denoted by ‘*b* ’. For example, "117 + 136=253" is true if and only if ‘117 + 236’ and ‘253’ denote the same number. And "Mark Twain is Samuel Clemens" is true if and only if ‘Mark Twain’ and ‘Samuel Clemens’ denote the same person. So the truth of "$a=b$" requires that the expressions flanking the identity sign denote the same object.

But Frege noticed that on this account of truth, the truth conditions for "$a=b$" are no different from the truth conditions for "$a=a$". For example, the truth conditions for "Mark Twain=Mark Twain" are the

same as those for "Mark Twain=Samuel Clemens"; not only do the names flanking the identity sign denote the same object in each case, but the object is the same between the two cases. The problem is that the cognitive significance (or meaning) of the two sentences differ. We can learn that "Mark Twain=Mark Twain" is true simply by inspecting it; but we can't learn the truth of "Mark Twain=Samuel Clemens" simply by inspecting it. Similarly, whereas you can learn that "117 + 136=117 + 136" and "the morning star is identical to the morning star" are true simply by inspection, you can't learn the truth of "117 + 136=253" and "the morning star is identical to the evening star" simply by inspection. In the latter cases, you have to do some arithmetical work or astronomical investigation to learn the truth of these identity claims.

So the puzzle Frege discovered is: if we cannot appeal to a difference in denotation of the terms flanking the identity sign, how do we explain the difference in cognitive significance between "*a*=*b*" and "*a*=*a*"?

Frege's Puzzle About Propositional Attitude Reports. Frege is generally credited with identifying the following puzzle about propositional attitude reports, even though he didn't quite describe the puzzle in the terms used below. A propositional attitude is a psychological relation between a person and a proposition. Belief, desire, intention, discovery, knowledge, etc., are all psychological relationships between persons, on the one hand, and propositions, on the other. When we report the propositional attitudes of others, these reports all have a similar logical form:

> *x* believes that *p*
> *x* desires that *p*
> *x* intends that *p*
> *x* discovered that *p*
> *x* knows that *p*

If we replace the variable '*x* ' by the name of a person and replace the variable '*p* ' with a sentence that describes the propositional object of their attitude, we get specific attitude reports. So by replacing '*x* ' by 'John' and '*p* ' by "Mark Twain wrote *Huckleberry Finn*" in the first example, the result would be the following specific belief report:

> John believes that Mark Twain wrote *Huckleberry Finn*.

To see the problem posed by the analysis of propositional attitude reports, consider what appears to be a simple principle of reasoning, namely, the Principle of Substitution. If a name, say *n*, appears in a true sentence S, and the identity sentence *n*=*m* is true, then the Principle of Substitution tells us that the substitution of the name *m* for the name *n* in S does not affect the truth of S. For example, let S be the true sentence "Mark Twain was an author", let *n* be the name 'Mark Twain', and let *m* be the name 'Samuel Clemens'. Then since the identity sentence "Mark Twain=Samuel Clemens" is true, we can substitute 'Samuel Clemens' for 'Mark Twain' without affecting the truth of the sentence. And indeed, the resulting sentence "Samuel Clemens was an author" is true. In other words, the following argument is valid:

Mark Twain was an author.
Mark Twain=Samuel Clemens.
Therefore, Samuel Clemens was an author.

Similarly, the following argument is valid.

4 > 3
4=8/2
Therefore, 8/2 > 3

In general, then, the Principle of Substitution seems to take the following form, where S is a sentence, *n* and *m* are names, and S(*n*) differs from S(*m*) only by the fact that at least one occurrence of *m* replaces *n*:

From S(*n*) and *n*=*m*, infer S(*m*)

This principle seems to capture the idea that if we say something true about an object, then even if we change the name by which we refer to that object, we should still be saying something true about that object.

But Frege, in effect, noticed the following counterexample to the Principle of Substitution. Consider the following argument:

John believes that Mark Twain wrote *Huckleberry Finn* .
Mark Twain=Samuel Clemens.
Therefore, John believes that Samuel Clemens wrote *Huckleberry Finn*.

This argument is not valid. There are circumstances in which the premises are true and the conclusion false. We have already described such circumstances, namely, one in which John learns the name ‘Mark Twain’ by reading *Huckleberry Finn* but learns the name ‘Samuel Clemens’ in the context of learning about 19th century American authors (without learning that the name ‘Mark Twain’ was a pseudonym for Samuel Clemens). John may *not* believe that Samuel Clemens wrote *Huckleberry Finn*. The premises of the above argument, therefore, do not logically entail the conclusion. So the Principle of Substitution appears to break down in the context of propositional attitude reports. The puzzle, then, is to say what causes the principle to fail in these contexts. Why aren't we still saying something true about the man in question if all we have done is changed the name by which we refer to him?

Frege's Theory of Sense and Denotation

To explain these puzzles, Frege suggested that in addition to having a denotation, names and descriptions also express a *sense*. The sense of a expression accounts for its cognitive significance---it is the way by

which one conceives of the denotation of the term. The expressions ‘4’ and ‘8/2’ have the same denotation but express different senses, different ways of conceiving the same number. The descriptions ‘the morning star’ and ‘the evening star’ denote the same planet, namely Venus, but express different ways of conceiving of Venus and so have different senses. The name ‘Pegasus’ and the description ‘the most powerful Greek god’ both have a sense (and their senses are distinct), but neither has a denotation. However, even though the names ‘Mark Twain’ and ‘Samuel Clemens’ denote the same individual, they express different senses. Using the distinction between sense and denotation, Frege can account for the difference in cognitive significance between identity statements of the form "a=a" and "a=b". The sense of the whole statement, on Frege's view, is a function of the senses of its component parts. Since the sense of ‘a’ differs from the sense of ‘b’, the components of "a=a" and "a=b" are different and so the sense of the whole expression will be different in the two cases. Since the sense of an expression accounts for its cognitive significance, Frege has an explanation of the difference in cognitive significance between "a=a" and "a=b", and thus a solution to the first puzzle.

Moreover, Frege proposed that when a term (name or description) follows a propositional attitude verb, it no longer denotes what it ordinarily denotes. Instead, Frege claims that in such contexts, a term denotes its ordinary sense. This explains why the Principle of Substitution fails for terms following the propositional attitude verbs in propositional attitude reports. The Principle asserts that truth is preserved when we substitute one name for another having the same denotation. But, according to Frege's theory, the names ‘Mark Twain’ and ‘Samuel Clemens’ denote different senses when they occur in the following sentences:

> John believes that Mark Twain wrote *Huckleberry Finn*.
> John believes that Samuel Clemens wrote *Huckleberry Finn*.

If they don't denote the same object, then there is no reason to think that substitution of one name for another would preserve truth.

Frege developed the theory of sense and denotation into a thoroughgoing philosophy of language. This philosophy can be explained, at least in outline, by considering a simple sentence such as "John loves Mary". In Frege's view, each word in this sentence is a name and, moreover, the sentence as a whole is a complex name. Each of these names has both a sense and a denotation. Then sense and denotation of the words are basic; but sense and denotation of the sentence as a whole can be described in terms of the sense and denotation of the words and the way in which those words are arranged in the sentence. Let us refer to the denotation and sense of the words as follows:

> **d**[j] refers to the denotation of the name ‘John’.
> **d**[m] refers to the denotation of the name ‘Mary’.
> **d**[L] refers to the denotation of the name ‘loves’.
> **s**[j] refers to the sense of the name ‘John’.
> **s**[m] refers to the sense of the name ‘Mary’.
> **s**[L] refers to the sense of the name ‘loves’.

We now work toward a theoretical description of the denotation of the sentence as a whole. On Frege's view, **d**[j] and **d**[m] are the real individuals John and Mary, respectively. **d**[L] is a function that maps **d**[m] (i.e., Mary) to a function which serves as the denotation of the predicate ‘loves Mary’. Let us refer to that function as **d**[Lm]. Now the function **d**[Lm] maps **d**[j] (i.e., John) to the denotation of the sentence "John loves Mary". Let us refer to the denotation of the sentence as **d**[jLm]. Frege identifies the denotation of a sentence as one of the two truth values. Because **d**[Lm] maps objects to truth values, it is a concept. Thus, **d**[jLm] is the truth value The True if the extension of the concept **d**[Lm] contains John; otherwise it is the truth value The False. So, on Frege's view, the sentence "John loves Mary" names a truth value.

The sentence "John loves Mary" also expresses a sense. Its sense may be described as follows. First, **s**[L] (the sense of the name "loves") is identified as a function. This function maps **s**[m] (the sense of the name "Mary") to the sense of the predicate ‘loves Mary’. Let us refer to the sense of ‘loves Mary’ as **s**[Lm]. Now the function **s**[Lm] maps **s**[j] (the sense of the name ‘John’) to the sense of the whole sentence. Let us call the sense of the entire sentence **s**[jLm]. Frege calls the sense of a sentence a *thought*, and whereas there are only two truth values, he supposes that there are an infinite number of thoughts.

On Frege's view, therefore, the sentences "4=8/2" and "4=4" both name the same truth value, but they express different thoughts. That is because **s**[4] is different from **s**[8/2]. Similarly, "Mark Twain=Mark Twain" and "Mark Twain=Samuel Clemens" denote the same truth value, but express different thoughts (since the sense of the names differ). Thus, Frege has a general account of the difference in the cognitive significance between identity statements of the form "*a*=*a*" and "*a*=*b*". Furthermore, recall that Frege proposed that terms following propositional attitude verbs denote not their ordinary denotations but rather the senses they ordinarily express. In fact, in the following propositional attitude report, not only do the words ‘Mark Twain’, ‘wrote’ and ‘*Huckleberry Finn* ’ denote their ordinary senses, but the entire sentence "Mark Twain wrote *Huckleberry Finn*" also denotes its ordinary sense (namely, a thought):

> John believes that Mark Twain wrote *Huckleberry Finn*.

Frege, therefore, would analyze this attitude report as follows: "believes that" denotes a function that maps the denotation of the sentence "Mark Twain wrote *Huckleberry Finn*" to a concept. In this case, however, the denotation of the sentence "Mark Twain wrote *Huckleberry Finn*" is not a truth value but rather a thought. The thought it denotes is different from the thought denoted by "Samuel Clemens wrote *Huckleberry Finn*" in the following propositional attitude report:

> John believes that Samuel Clemens wrote *Huckleberry Finn*.

Since the thought denoted by "Samuel Clemens wrote *Huckleberry Finn*" in this context differs from the thought denoted by "Mark Twain wrote *Huckleberry Finn*" in the same context, the concept denoted by ‘believes that Mark Twain wrote *Huckleberry Finn*’ is a different concept from the one denoted by ‘believes that Samuel Clemens wrote *Huckleberry Finn*’. One may consistently suppose that the concept denoted by the former predicate maps John to The True whereas the the concept denoted by the latter

predicate does not. Frege's analysis therefore preserves our intuition that John can believe that Mark Twain wrote *Huckleberry Finn* without believing that Samuel Clemens did. It also preserves the Principle of Substitution---the fact that one cannot substitute "Samuel Clemens" for "Mark Twain" when these names occur after propositional attitude verbs does not constitute evidence against the Principle. For if Frege is right, names do not have their usual denotation when they occur in these contexts.

Principia Mathematica

Principia Mathematica is the landmark work on mathematical logic and the foundations of mathematics written by Alfred North Whitehead and Bertrand Russell. It was first published in three volumes, in 1910, 1912 and 1913. Written as a defense of logicism (the view that mathematics is in some significant sense reducible to logic), the book was instrumental in popularizing modern mathematical logic. Next to Aristotle's *Organon*, it is the most influential book on logic ever written. Interested readers may wish to view the Title page of the 1st edition of *Principia Mathematica*, Volume 1 or the Cover of the 1st edition of *Principia Mathematica to *56*.

History of *Principia Mathematica*

Logicism is the view that (some or all of) mathematics can be reduced to (formal) logic, and it is often explained as a two-part thesis. First, it consists of the thesis that all mathematical truths can be translated into logical truths or, in other words, that the vocabulary of mathematics constitutes a proper subset of that of logic. Second, it consists of the thesis that all mathematical proofs can be recast as logical proofs or, in other words, that the theorems of mathematics constitute a proper subset of those of logic. In Bertrand Russell's words, it is the logicist's goal "to show that all pure mathematics follows from purely logical premises and uses only concepts definable in logical terms" (Russell [1955], p. 57).

In its essentials, this thesis was first advocated in the late 17th century by Gottfried Leibniz. Later, the idea was defended in much greater detail by Gottlob Frege. During the critical movement initiated in the 1820s, mathematicians such as Bernard Bolzano, Niels Abel, Louis Cauchy and Karl Weierstrass had succeeded in eliminating much of the vagueness and many of the contradictions present in the mathematical theories of their day. By the late 1800s, William Hamilton had also introduced ordered

couples of reals as the first step in supplying a logical basis for the complex numbers, and Weierstrass, Richard Dedekind and Georg Cantor had all developed methods for founding the irrationals in terms of the rationals. Using work by H.G. Grassmann and Dedekind, Guiseppe Peano had also gone on to develop a theory of the rationals based on his now famous axioms for the natural numbers. Thus, by Frege's day it was generally recognized that a large portion of mathematics could be derived from a relatively small set of primitive notions.

Even so, it was not until 1879, when Frege developed the necessary logical apparatus, that the project of logicism could be said to have become technically viable. Following another five years' work, Frege arrived at the definitions necessary for logicising arithmetic. During the 1890s he worked on many of the essential derivations. However, with the discovery of paradoxes such as Russell's paradox at the turn of the century, it appeared that additional resources would be required if logicism were to succeed.

By 1903, both Whitehead and Russell had come to the same conclusion. By this time, both men were also in the initial stages of preparing second volumes to earlier books on related topics: Whitehead's 1898 *A Treatise on Universal Algebra* and Russell's 1903 *The Principles of Mathematics.* Since their research overlapped considerably, they began collaboration on what was eventually to become *Principia Mathematica.*

Unfortunately, after almost a decade of difficult work on the part of both men, Cambridge University Press concluded that publishing *Principia* would result in an estimated loss of approximately 600 pounds. Although the press agreed to assume half this amount and the Royal Society agreed to donate another 200 pounds, that still left a 100-pound deficit. Only by each contributing 50 pounds were the authors able to see their work through to publication.

Today there is not a major academic library anywhere in the world that does not possess a copy of this landmark publication.

Significance of *Principia Mathematica*

Principia's main goal of showing the detailed deduction of mathematics from logic proved to be controversial. Primarily at issue were the kinds of assumptions that Whitehead and Russell used to complete their project. Although *Principia* succeeded in providing detailed derivations of major theorems in set theory, finite and transfinite arithmetic, and elementary measure theory, two axioms in particular were arguably non-logical in character: the axiom of infinity and the axiom of reducibility. The axiom of infinity assumed that there exists an infinity of objects. Thus, it made the kind of assumption that is generally thought to be empirical rather than logical in nature. The axiom of reducibility was introduced as a means of overcoming the not completely satisfactory effects of the theory of types, the theory that Russell and Whitehead used to restrict the notion of a well-formed expression, and so to avoid the paradoxes. Although technically feasible, many critics claimed that the axiom of reducibility was simply too ad hoc to be justified philosophically. As a result, the question of whether mathematics could be reduced to logic, or whether it could be reduced only to set-theory, remained open.

Despite these criticisms, *Principia Mathematica* proved to be remarkably influential in at least three other ways. First, it popularized modern mathematical logic to an extent undreamt of by its authors. By using a notation superior in many ways to that of Frege, Whitehead and Russell managed to convey the remarkable expressive power of modern logic in a way that previous writers had been unable to achieve. Second, by exhibiting so clearly the deductive power of the new logic, Whitehead and Russell were also able to show how powerful the modern idea of a formal system could be. Third, *Principia Mathematica* reaffirmed clear and interesting connections between logicism and two main branches of traditional philosophy, namely metaphysics and epistemology, thus initiating new and interesting work in both these and other areas.

Thus, not only did *Principia* introduce a wide range of philosophically rich notions (such as propositional function, logical construction, and type theory), it also set the stage for the discovery of classical metatheoretic results (such as those of Kurt Gödel and others) and initiated a tradition of common technical work in fields as diverse as philosophy, mathematics, linguistics, economics and computer science.

Contents of *Principia Mathematica*

Principia Mathematica appeared in three volumes which together are divided into six parts. Volume 1 begins with a lengthy Introduction containing sections entitled "Preliminary Explanations of Ideas and Notations", "The Theory of Logical Types" and "Incomplete Symbols". It also contains Part I, entitled "Mathematical Logic", which contains sections on "The Theory of Deduction", "Theory of Apparent Variables", "Classes and Relations", "Logic of Relations", and "Products and Sums of Classes"; and Part II, entitled "Prolegomena to Cardinal Arithmetic", which contains sections on "Unit Classes and Couples", "Sub-Classes, Sub-Relations, and Relative Types", "One-Many, Many-One and One-One Relations", "Selections", and "Inductive Relations".

Volume 2 begins with a "Prefatory Statement of Symbolic Conventions". It then continues with Part III, entitled "Cardinal Arithmetic", which itself contains sections on "Definition and Logical Properties of Cardinal Numbers", "Addition, Multiplication and Exponentiation", and "Finite and Infinite"; Part IV, entitled Relation-Arithmetic", which contains sections on "Ordinal Similarity and Relation-Numbers", "Addition of Relations, and the Product of Two Relations", "The Principle of First Differences, and the Multiplication and Exponentiation of Relations", and "Arithmetic of Relation-Numbers"; and the first half of Part V, entitled "Series", which contains sections on "General Theory of Series", "On Sections, Segments, Stretches, and Derivatives", and "On Convergence, and the Limits of Functions".

Volume 3 continues Part V with sections on "Well-Ordered Series", "Finite and Infinite Series and Ordinals", and "Compact Series, Rational Series, and Continuous Series". It also contains Part VI, entitled "Quantity", which itself contains sections on "Generalization of Number", "Vector-Families", "Measurement", and "Cyclic Families".

A fourth volume, on geometry, was planned but never completed. Even so, the book remains one of the great scientific documents of the twentieth century.

Alfred North Whitehead

Alfred North Whitehead (b.1861 - d.1947), British mathematician, logician and philosopher best known for his work in mathematical logic and who, in collaboration with Bertrand Russell, authored the landmark three-volume *Principia Mathematica* (1910, 1912, 1913).

Although there are significant continuities throughout his thought, Whitehead's intellectual life is often divided into three periods. The first corresponds roughly with his time at Cambridge, from 1884 to 1910, during which he worked primarily on logic and mathematics. The second corresponds roughly with his time at London, from 1910 to 1924, during which he concentrated mainly on issues in the philosophy of science. The third corresponds roughly with his time at Harvard, from 1924 onward, during which he worked on more general issues in philosophy, including the development of a comprehensive metaphysical system which has come to be known as process philosophy.

Whitehead's Chronology

A short chronology of the major events in Whitehead's life is as follows:

- (1861) Born February 15 in Ramsgate, Isle of Thanet, Kent, England.
- (1880) Enters Trinity College, Cambridge with a scholarship in mathematics.
- (1884) Elected a Fellow in Mathematics at Trinity.
- (1891) Marries Evelyn Wade.
- (1903) Elected a Fellow of the Royal Society as a result his work on universal algebra.
- (1910) Moves to University College London.
- (1914) Appointed Professor of Applied Mathematics at the Imperial College of Science and Technology.
- (1924) Appointed Professor of Philosophy at Harvard University.
- (1931) Elected a Fellow of the British Academy.
- (1937) Retires from Harvard.
- (1945) Awarded Order of Merit.
- (1947) Dies December 30 in Cambridge, Massachusetts, USA.

For a chronology of Whitehead's major publications, consult the section below entitled Whitehead's Writings.

Whitehead's Philosophical Influence

Whitehead's philosophical influence can be felt in all three of the main areas in which he worked -- logic and the foundations of mathematics, the philosophy of science, and metaphysics -- as well as in other areas such as ethics, education and religion.

Whitehead began his academic career at Trinity College, Cambridge, where, starting in 1885, he taught for twenty-five years. In 1890 Bertrand Russell arrived as a student at Trinity and during the 1890s the two men came into regular contact with one another. According to Russell, "Whitehead was extraordinarily perfect as a teacher"[1] and Whitehead soon became something of a mentor to the younger man.

By the early 1900s, both men had completed books on the foundations of mathematics. Whitehead's 1898 *A Treatise on Universal Algebra* had resulted in his election to the Royal Society. Russell's 1903 *The Principles of Mathematics* had marked a decisive break from his earlier neo-Kantian work, such as his 1897 *An Essay on the Foundations of Geometry*. Since the research for a proposed second volume of Russell's *Principles* overlapped considerably with Whitehead's own research for the proposed second volume of his *Universal Algebra*, the two men began collaboration on what was eventually to become *Principia Mathematica* (1910, 1912, 1913). According to Whitehead, they initially expected the research

to take about a year to complete. In the end, they worked together on the project for a full decade.

Logicism, the theory that mathematics is in some important sense reducible to logic, consists of two main theses. The first is that all mathematical truths can be translated into logical truths or, in other words, that the vocabulary of mathematics constitutes a proper subset of that of logic. The second is that all mathematical proofs can be recast as logical proofs or, in other words, that the theorems of mathematics constitute a proper subset of those of logic.

Like Gottlob Frege, Whitehead and Russell took the view that numbers could be identified with sets of sets, and that number-theoretic operations could be explained in terms of set theoretic operations such as intersection, union, and difference. Although Whitehead and Russell were able to provide many detailed derivations of major theorems in set theory, finite and transfinite arithmetic, and elementary measure theory, the issue of whether set theory itself can be said to have been successfully reduced to logic remained controversial.

Following the completion of *Principia*, Whitehead and Russell began to go their separate ways. Perhaps inevitably, Russell's anti-war activities during World War I (in which Whitehead lost his youngest son) also led to something of a split between the two men. Nevertheless, they remained on relatively good terms for the rest of their lives.

At the University of London, Whitehead turned his attention to issues in the philosophy of science. Of particular note was his rejection of the idea that each object has a simple spatial or temporal location. Instead, Whitehead advocated the view that all objects should be understood as fields having both temporal and spatial extensions. For example, just as we cannot perceive a Euclidean point that has position but no magnitude, or a line that has length but no breadth, it is impossible, says Whitehead, to conceive of a simple spatial or temporal location. To think that we can do so involves what he called "The Fallacy of Misplaced Concreteness," the error of mistaking the abstract for the concrete.[2]

As Whitehead explains, "I shall argue that among the primary elements of nature as apprehended in our immediate experience, there is no element whatever which possesses this character of simple location. ... [Instead,] I hold that by a process of constructive abstraction we can arrive at abstractions which are the simply-located bits of material, and at other abstractions which are the minds included in the scientific scheme."[3]

Whitehead's basic idea was that we obtain the abstract idea of a spatial point by considering a real-life series of volumes extending over each other, for example, a nested series of Russian dolls or a nested series of pots and pans. However, it would be a mistake to think of a spatial point as being anything more than an abstraction; instead, real positions involve the entire series of extended volumes. As Whitehead himself puts it, "In a certain sense, everything is everywhere at all times. For every location involves an aspect of itself in every other location. Thus every spatio-temporal standpoint mirrors the world."[4]

Further, according to Whitehead, every real-life object may be understood as a similarly constructed

series of events and processes. It is this latter idea that Whitehead later systematically elaborates in his imposing *Process and Reality* (1929), going so far as to suggest that process, rather than substance, should be taken as the fundamental metaphysical constituent of the world. Underlying this work was also the basic idea that, if philosophy is to be successful, it must explain the connection between objective, scientific and logical descriptions of the world and the more everyday world of subjective experience.

While at London, Whitehead also became involved in many practical aspects of tertiary education, serving as Dean of the Faculty of Science and holding several other senior administrative posts. Many of the essays in his *The Aims of Education and Other Essays* (1929) date from this time. It was also during his time in London that Whitehead also published several less well known books, including *An Inquiry Concerning the Principles of Natural Knowledge* (1919), *The Concept of Nature* (1920), and *The Principle of Relativity* (1922).

Upon being offered an appointment at Harvard, Whitehead moved to the United States in 1924. Given his prior training in mathematics and in the physical sciences, it was sometimes joked that the first philosophy lectures he ever attended were those that he delivered at Harvard in his new role as Professor of Philosophy. A year later he also delivered Harvard's prestigious Lowell Lectures which formed the basis for his first primarily metaphysical book, *Science and the Modern World* (1925). In it he again introduced several themes which later found fuller expression in *Process and Reality*. The same was true of the 1927/28 Gifford Lectures at the University of Edinburgh on which *Process and Reality* came to be based.

In *Process and Reality*, rather than assuming substance as the basic metaphysical category, Whitehead introduces the notion of an *actual occasion*. On Whitehead's view, an actual occasion is not an enduring substance, but a process of becoming. As Donald Sherburne points out, "It is customary to compare an actual occasion with a Leibnizian monad, with the caveat that whereas a monad is windowless, an actual occasion is ‘all window’. It is as though one were to take Aristotle's system of categories and ask what would result if the category of substance were displaced from its preeminence by the category of relation ... ."[5] As Whitehead himself explains, his "philosophy of organism is the inversion of Kant's philosophy ... For Kant, the world emerges from the subject; for the philosophy of organism, the subject emerges from the world."[6]

Significantly, this view runs counter to the more traditional view of material substance: "There persists," says Whitehead, "[a] fixed scientific cosmology which presupposes the ultimate fact of an irreducible brute matter, or material, spread through space in a flux of configurations. In itself such a material is senseless, valueless, purposeless. It just does what it does do, following a fixed routine imposed by external relations which do not spring from the nature of its being. It is this assumption that I call ‘scientific materialism.’ Also it is an assumption which I shall challenge as being entirely unsuited to the scientific situation at which we have now arrived."[7]

The assumption of scientific materialism is effective in many contexts, says Whitehead, only because it directs our attention to a certain class of problems that lend themselves to analysis within this framework.

However, scientific materialism is less successful when addressing issues of teleology and when trying to develop a comprehensive, intergrated picture of the universe as a whole. According to Whitehead, recognition that the world is organic rather than materialistic is therefore essential, and this change in viewpoint can result as easily from attempts to understand modern physics as from attempts to understand human psychology and teleology. Says Whitehead, "Mathematical physics presumes in the first place an electromagnetic field of activity pervading space and time. The laws which condition this field are nothing else than the conditions observed by the general activity of the flux of the world, as it individualises itself in the events."[8]

The end result is that Whitehead concludes that "nature is a structure of evolving processes. The reality is the process."[9]

Whitehead's ultimate attempt to develop a metaphysical unification of space, time, matter, events and teleology has proved to be controversial. In part this may be because of the connections that Whitehead saw between his metaphysics and traditional theism. According to Whitehead, religion is concerned with permanence amid change, and can be found in the ordering we find within nature, something he sometimes called the "primordial nature of God". Thus although not especially influential among contemporary Anglo-American secular philosophers, his metaphysical ideas have had greater influence among many theologians and philosophers of religion.

Whitehead's Writings

Whitehead's principal publications include the following:

- (1898) *A Treatise on Universal Algebra*, Cambridge: Cambridge University Press.
- (1906) *On Mathematical Concepts of the Material World*, London: Dulau.
- (1906) *The Axioms of Projective Geometry*, Cambridge: Cambridge University Press.
- (1907) *The Axioms of Descriptive Geometry*, Cambridge: Cambridge University Press.
- (1910, 1912, 1913) (with Bertrand Russell) *Principia Mathematica*, 3 vols, Cambridge: Cambridge University Press. Second edition, 1925 (Vol. 1), 1927 (Vols 2, 3). Abridged as *Principia Mathematica to *56*, Cambridge: Cambridge University Press, 1962.
- (1911) *An Introduction to Mathematics*, London: Williams & Norgate.
- (1919) *An Enquiry Concerning the Principles of Natural Knowledge*, Cambridge: Cambridge University Press.
- (1920) *The Concept of Nature*, Cambridge: Cambridge University Press.
- (1922) *The Principle of Relativity With Applications to Physical Science*, Cambridge: Cambridge University Press.
- (1925) *Science and the Modern World*, Cambridge: Cambridge University Press.
- (1926) *Religion in the Making*, New York: Macmillan.
- (1927) *Symbolism, Its Meaning and Effect*, New York: Macmillan.
- (1929) *The Aims of Education and Other Essays*, New York: Macmillan.
- (1929) *The Function of Reason*, Princeton: Princeton University Press.

- (1929) *Process and Reality,* New York: Macmillan.
- (1933) *Adventures of Ideas,* New York: New American.
- (1934) *Nature and Life,* Chicago: University of Chicago Press.
- (1938) *Modes of Thought*, New York: Macmillan.
- (1947) *Essays in Science and Philosophy,* New York: Philosophical Library.
- (1947) *The Wit and Wisdom of Whitehead,* Boston: Beacon Press.

Process Philosophy

The philosophy of process is a venture in metaphysics, the general theory of reality. Its concern is with what exists in the world and with the terms of reference in which this reality is to be understood and explained. The task of metaphysics is, after all, to provide a cogent and plausible account of the nature of reality at the broadest, most synoptic and comprehensive level. And it is to this mission of enabling us to characterize, describe, clarify and explain the most general features of the real that process philosophy addresses itself in its own characteristic way. The guiding idea of its approach is that natural existence consists in and is best understood in terms of *processes* rather than *things* -- of modes of change rather than fixed stabilities. For processists, change of every sort -- physical, organic, psychological -- is the pervasive and predominant feature of the real.

Process philosophy diametrically opposes the view -- as old as Parmenides and Zeno and the Atomists of Pre-Socratic Greece -- that denies processes or downgrades them in the order of being or of understanding by subordinating them to substantial things. By contrast, process philosophy pivots on the thesis that the processual nature of existence is a fundamental fact with which any adequate metaphysic must come to terms.

Process philosophy puts processes at the forefront of philosophical and specifically of ontological concern. Process should here be construed in pretty much the usual way -- as *a sequentially structured sequence of successive stages or phases*. Three factors accordingly come to the fore:

1. That a process is a complex -- a unity of distinct stages or phases. A process is always a matter of now this, now that.
2. That this complex has a certain temporal coherence and unity, and that processes accordingly have an ineliminably temporal dimension.
3. That a process has a structure, a formal generic format in virtue of which every concrete process is equipped with a shape or format.

From the time of Aristotle, Western metaphysics has had a marked bias in favor of *things* or *substances*. However, another variant line of thought was also current from the earliest times onward. After all, the concentration on perduring physical *things* as existents in nature slights the equally good claims of another ontological category, namely processes, events, occurrences -- items better indicated by verbs than nouns. And, clearly, storms and heat-waves are every bit as real as dogs and oranges.

What is characteristically definitive of *process* philosophizing as a distinctive sector of philosophical

tradition is not simply the commonplace recognition of natural process as the active initiator of what exists in nature, but an insistence on seeing process as constituting an essential aspect of everything that exists -- a commitment to the fundamentally processual nature of the real. For the process philosopher is, effectively by definition, one who holds that what exists in nature is not just originated and sustained by processes but is in fact ongoingly and inexorably *characterized* by them. On such a view, process is both pervasive in nature and fundamental for its understanding.

---

1. Historical Aspects

Like so much else in the field, process philosophy began with the ancient Greeks. The Greek theoretician Heraclitus of Ephesus (b. ca. 540 B.C.) -- known even in antiquity as "the obscure" -- is universally recognized as the founder of the process approach. His book "On Nature" depicted the world as a manifold of opposed forces joined in mutual rivalry, interlocked in constant strife and conflict. Fire, the most changeable and ephemeral of these elemental forces, is the basis of all: "This world-order . . . is . . . an ever living fire, kindling in measures and going out in measures" (Fr. 217, Kirk-Raven-Schofield). The fundamental "stuff" of the world is not a material substance of some sort but a natural process, namely "fire," and all things are products of its workings (*puros tropai*). The variation of different states and conditions of fire -- that most process-manifesting of the four traditional Greek elements -- engenders all natural change. For fire is the destroyer and transformer of things and "All things happen by strife and necessity" (Fr. 211, *ibid*). And this changeability so pervades the world that "one cannot step twice into the same river" (Fr. 215, *ibid*). As Heraclitus saw it, reality is at bottom not a constellation of *things* at all, but one of *processes*: we must at all costs avoid the fallacy of substantializing nature into perduring things (substances) because it is not stable things but fundamental forces and the varied and fluctuating activities

which they produce that make up this world of ours. Process is fundamental: the river is not an *object*, but an ever-changing flow; the sun is not a *thing*, but a flaming fire. Everything in nature is a matter of process, of activity, of change. Heraclitus taught that *panta rhei* ("everything flows") and this principle exerted a profound influence on classical antiquity. Even Plato, who did not much like the principle ("like leaky pots" he added at *Cratylus* 440 C), came to locate his exception to it -- the enduring and changeless "ideas" -- in a realm wholly removed from the domain of material reality.

Heraclitus may accordingly be seen as the founding father of process philosophy, at any rate in the intellectual tradition of the West. And the static system of Parmenides affords its sharpest contrast and most radical opposition. However, the paradigm substance philosophy of classical antiquity was the atomism of Leucippus and Democritus and Epicurus, which pictured all of nature as composed of unchanging and inert material atoms whose only commerce with process was an alteration of their positioning in space and time. Here the *properties* of substances are never touched by change, which effects only their *relations*. It was this sort of view that Heraclitus preeminently sought to oppose.

In recent years, "process philosophy" has virtually become a code-word for the doctrines of Alfred North Whitehead and his followers. But of course, this cannot really be what process philosophy actually is. If there indeed is a "philosophy" of process, it must pivot not a *thinker* but on a *theory*. What is at issue must, in the end, be a philosophical position that has a larger life of its own, apart from any particular exposition or expositor. And in fact process philosophy is a well-defined and influential tendency of thought that can be traced back through the history of philosophy to the days of the Pre-Socratics. Its leading exponents were Heraclitus, Leibniz, Bergson, Peirce, and William James -- and it ultimately moved on to include Whitehead and his school (Charles Hartshorne, Paul Weiss), but also other 20th Century philosophers such as Samuel Alexander, C. Lloyd Morgan, and Andrew Paul Ushenko.

2. How Process Philosophy Proceeds

Against this historical background, "process philosophy" may be understood as a doctrine invoking certain basic propositions: (1) That time and change are among the principal categories of metaphysical understanding, (2) That process is a principal category of ontological description, (3) That process is more fundamental, or at any rate not less fundamental than things for the purposes of ontological theory, (4) That several if not all of the major elements of the ontological repertoire (God, nature-as-a whole, persons, material substances) are best understood in process linked terms, and (5) That contingency, emergence, novelty, and creativity are among the fundamental categories of metaphysical understanding. A process philosopher, accordingly, is someone for whom temporality, activity, and change -- of alteration, striving, passage, and novelty-emergence -- are the cardinal factors for our understanding of the real.

The demise of classical atomism brought on by the dematerialization of physical matter through the rise of the quantum theory brings much aid and comfort to a process-oriented metaphysics. Matter in the small, as contemporary physics conceives it, is not a Rutherfordian planetary system of particle-like objects, but a collection of fluctuating processes organized into stable structures (insofar as there is indeed

stability at all) by statistical regularities -- i.e., by regularities of comportment at the level of aggregate phenomena. Twentieth century physics has thus turned the tables on classical atomism. Instead of very small *things* (atoms) combining to produce standard processes (windstorms and such) modern physics envisions very small processes (quantum phenomena) combining to produce standard things (ordinary macro-objects) as a result of their *modus operandi*.

For the process philosopher, the classical principle *operari sequitur esse* (functioning follows upon being) is reversed: his motto is the reverse *esse sequitur operari*. As he sees it, all is in the final analysis the product of processes. Process thus has priority over product -- both ontologically and epistemically. As process philosophers see it, processes are basic and things derivative, because it takes a mental process (of separation) to extract "things" from the blooming buzzing confusion of the world's physical processes. For process philosophy, what a thing *is* consists in what it *does*.

And insofar as reality itself is a vast macroprocess embracing a diversified manifold of microprocesses novelty, innovation, and the emergence of new focus is an inherent feature of the cosmic scene.

3. An Evolutionary Perspective

Evolution is an emblematic and paradigmatic process for process philosophy. For not only is evolution a process that makes philosophers and philosophy possible, but it provides a clear model for how processual novelty and innovation comes into operation in nature's self-engendering and self-perpetuating scheme of things. Evolution, be it of organism or of mind, of subatomic matter or of the cosmos as a whole, reflects the pervasive role of process which philosophers of this school see as central both to the nature of our world and to the terms in which it must be understood. Change pervades nature. The passage of time leaves neither individuals nor types (species) of things statically invariant. Process at once destabilizes the world and is the cutting-edge of advance to novelty. And evolution of every level, physical, biological, and cosmic carries the burden of the work here. But does it work blindly?

On the issue of purposiveness in nature, process philosophers divide into two principal camps. On the one side is the naturalistic (and generally secularist) wing that sees nature's processuality as a matter of an inner push or nisus to something new and different. On the other side is the teleological (and often theological) wing that sees nature's processuality as a matter of teleological directedness towards a positive destination. Both agree in according a central role to novelty and innovation in nature. But the one (naturalistic) wing sees this in terms of chance-driven randomness that leads away from the settled formulations of an established past, while the other (teleological) wing sees this in terms of a goal-directed purposiveness preestablished by some value-geared directive force.

Process philosophy correspondingly has a complex, two sided relationship with the theory of evolution. For secular, atheological processists evolution typifies the creative workings of a self-sustaining nature that dispenses with the services of God. For theological processists like Teilhard de Chardin, evolution exhibits God's handwriting in the book of nature. But processists of all descriptions see evolution not only as a crucial instrument for understanding the role of intelligence in the world's scheme of things but

also as a key aspect of the world's natural development. And, more generally, the evolutionary process has provided process philosophy with one of its main models for how large scale collective processes (on the order of organic development at large) can inhere in and result from the operation of numerous small-scale individual processes (on the order of individual lives), thus accounting for innovation and creativity also on a macro-level scale.

But there is one further complexity here. Where human intelligence is concerned, biological evolution is undoubtedly Darwinian, with teleologically blind natural selection operating with respect to teleologically blind random mutations. Cultural evolution, on the other hand, is generally Teilhardian, governed by a rationally-guided selection among purposefully devised mutational variations. Taken in all, cognitive evolution involves both components, superimposing rational selection on biological selection. Our cognitive capacities and faculties are part of the natural endowment we owe to biological evolution. But our cognitive methods, procedures, standards, and techniques are socio-culturally developed resources that evolve through *rational* selection in the process of cultural transmission through successive generations. Our cognitive hardware (mechanisms and capacities) develops through Darwinian natural selection, but our cognitive software (the methods and procedures by which we transact our cognitive business) develops in a Teilhardian process of rational selection that involves purposeful intelligence-guided variation and selection. Biology produces the instrument, so to speak, and culture writes the music -- where obviously the former powerfully constrains the latter. (You cannot play the drums on a piano.)

The ancient Greeks grappled with the question: Is anything changeless, eternal, and exempt from the seemingly all-destructive ravages of time. Rejecting the idea of eternal material atoms, Plato opted for eternal changeless universals ("form," "ideas") and the Stoics for eternal, changeless laws. But the world-picture of modern science has seemingly blocked these solutions. For, as it sees the matter, species (natural kinds) are also children of time, not changelessly present but ever-changingly emergent under the aegis of evolutionary principles. The course of cosmic evolution brings nature's laws also within the orbit of process, endowing these laws with a developmental dimension, (where, after all, was genetics in the microsecond after the big bang?). For process philosophy, nothing is eternal and secure from the changes wrought by time and its iron law that everything that comes into being must perish, so that mortality is omnipresent and death's cold hand is upon all of nature -- laws as well as things.

However, process philosophy does not see this gloomy truth as the end of the story. For process philosophy has always looked to evolutionary theory to pull the plum of collective progress from the pie of distributive mortality. In the small -- item by item -- nature's processes are self-canceling: what arises in the course of time perishes in the course of time. But nevertheless the overall course of processual change tends to the development of an ever richer, more complex and sophisticated condition of things on the world's ample stage. For there are processes and processes: processes of growth and decay, of expanding and contracting, of living and dying. Recognizing that this is so, process philosophy has always accentuated the positive and worn a decidedly optimistic mien. For it regards nature's microprocesses as components of an overall macroprocess whose course is upwards rather than downwards, so to speak. Hitching its wagon to the star of a creative evolutionism, process philosophy sees nature as encompassing creative innovation, productive dynamism and an emergent development of richer, more complex and sophisticated forms of natural existence.

To be sure, there are, in theory, both productive and destructive processes, degeneration and decay being no less prominent in nature than growth and development. Historically, however, most process philosophers have taken a decidedly optimistic line and have envisioned a close relationship between *process* and *progress*. For them, this relationship is indicated by the macro-process we characterize as evolution. At every level of world history -- the cosmic, the biological, the social, the intellectual -- process philosophers have envisioned a developmental dynamic in which later is *better* -- somehow superior in being more differentiated and sophisticated. Under the influence of Darwinian evolutionism, most process philosophers have envisioned a course of temporal development within which value is somehow survival-facilitative so that the arrangements which do succeed in establishing and perpetuating themselves will as a general tendency manage to have done so because they represent actual improvements in one way of another. (A decidedly optimistic tenor has prevailed throughout process philosophy.)

After all, differentiation is sophistication; detail is enrichment. The person who merely sees a bird does not see as much as the person who sees a finch, and she in turn does not see as much as the person who sees a Darwin finch. The realization and enhancement of detail bestows not just complexification as such but also sophistication. As process philosophy sees it, the world's processuality involves not only change but improvement -- the evolutionary realization -- at large and on the whole -- of what is not only different but also in some way better. Accordingly, novelty and fruitfulness compensate for transiency and mortality in process philosophy's scheme of things.

4. An Instructive Application

Recourse to process is a helpful device for dealing with the classical problem of universals. We are surrounded on all sides by items more easily conceived of as processes than as substantial things -- not only physical items like a magnetic field or an *aurora borealis*, but also conceptual artifacts like letters of the alphabet, words, and statements. That purported universal -- the opening line of a play, say, or a shade of phenomenal red -- now ceases to be a mysterious *object* of some sort and becomes a specifiable feature of familiar processes (readings, perceivings, imaginings). How distinct minds can perceive the same universal is now no more mysterious than how distinct walkers can share the same limp -- it is a matter of actions proceeding in a certain particular way. Since processes are structural in nature, universals are now pulled down from the Platonic realm to become generic features of the ways in which we concretely conduct our cognitive affairs.

The philosophy of mind is another strongpoint of process philosophizing. It feels distinctly uncomfortable to conceptualize *people* (persons) as *things* (substances) -- oneself above all -- because we resist flat-out identification with our bodies. However, there is no problem with experiential access to the processes and patterns of process that characterize us personally -- our doings and undergoings, either individually or patterned into talents, skills, capabilities, traits, dispositions, habits, inclinations, and tendencies to action and inaction are, after all, what characteristically define a person as the individual he or she is. Once we conceptualize the core "self" of a person as a unified manifold of actual and potential process -- of action

and capacities, tendencies, and dispositions to action (both physical and psychical) -- then we thereby secure a concept of personhood that renders the self or ego experientially accessible, seeing that experiencing itself simply *consists* of such processes. What makes my experience mine is not some peculiar qualitative character that it exhibits but simply its forming part of the overall ongoing process that defines and constitutes my life. The unity of person is a unity of experience -- the coalescence of all of one's diverse micro-experience as part of one unified macro-process. (It is the same sort of unity of process that links each minute's level into a single overall journey.) On this basis, the Humean complaint -- "One experiences feeling this and doing that, but one never experiences *oneself*" -- is much like the complaint of the person who says "I see him picking up that brick, and mixing that batch of mortar, and troweling that brick into place, but I never see him building a wall." Even as "building the wall" just exactly *is* the complex process that is *composed* of those various activities, so -- from the process point of view -- one's self just *is* the complex process *composed* of those various physical and psychic experiences and actions in their systemic interrelationship.

5. Diversity/Complexity

Like any philosophical tendency -- realism, idealism, materialism, etc. -- process philosophy is a fundamentally prismatic complex and has internal variations. The difference at issue is rooted in the issue of what type of process is taken as paramount and paradigmatic. Some contributors (especially A. N. Whitehead and Henri Bergson) see organic processes as central and other sorts of processes as modeled on or superengrafted upon them -- the conception of an all-integrating physical field being pivotal even for Whitehead's organic/biological reflections. Others (especially William James) based their ideas of process on a psychological model and saw human thought as idealistically paradigmatic. Methodologically, on the other hand, some (e.g. Whitehead) articulated their process philosophy in essentially scientific terms, while others (esp. Bergson) relied more on intuition and indeed an almost mystical sort of sympathetic apprehension. And then too, of course, there are cultural processists like John Dewey. But such differences notwithstanding there are family-resemblance commonalties of theme and emphasis that nevertheless leave the teachings of the several processists in the position of variations on a common approach. So in the end it is -- or should be -- clear that the unity of process philosophy is not doctrinal but thematic; it is not a consensus or a thesis but rather a mere diffuse matter of type and approach.

Accordingly, process philosophy as such is something rather schematic. There are distinct approaches to implementing its pivotal idea of the pervasiveness and fundamentality of process, ranging from a materialism of physical processes (as with Boscovitch) to a speculative idealism of psychic processes (as in some versions of Indian philosophy). There are rather different ways of being a process philosopher, varying drastically according to the nature of one's ideas regarding what process is all about. In historical perspective, process philosophy has accordingly run a somewhat meandering course that traces back more to the origins of philosophy in the days of Pre-Socratic philosophy.

As such considerations indicate, the process approach has many assets. But it has significant liabilities as well. It is not unfair to the historical situation to say that process philosophy at present remains no more

than a glint in the mind's eye of various philosophers. A full-fledged development of the process doctrine simply does not yet exist as an accomplished fact, its development to the point where it can be compared with other major philosophical projects like materialism or absolute idealism still remains to be realized.

The process approach has been a particularly important development in and for American philosophy -- especially owing to its increasingly close linkage to pragmatism in such thinkers as Peirce, James, and Dewey. In recent decades the great majority of its principal exponents have done their philosophical work in the United States, and it is here that interest in this approach to philosophy has been the most intense and extensive, constituting a considerable sub-sector within American philosophy at large. Like American philosophy in general, process philosophy is too complex and diversified an enterprise to be captured or even dominated by any one school of thought; it is a highly diversified manifold that encompasses tendencies of thought representing a wide variety of sources.

Regrettably, authors of histories and surveys not infrequently fail to give process philosophy the recognition that is its due. For example, the otherwise excellent survey of American philosophy by the able French scholar Gerard Deledalle omits all mention of process philosophy as such and takes only perfunctory notice of Whitehead in an Appendix. To take this line is not, perhaps, to give us Hamlet without the ghost, but is at least tantamount to omitting Horatio.

6. Strawson's Critique

P. F. Strawson has argued in his influential book on metaphysics that processism in all its versions is doomed to failure because physical objects -- and, in particular, material bodies -- are requisites for the idea of identifiable particulars in a way that is virtually indispensable to any viable metaphysical position. Strawson maintains that the identification of particulars in communication between speakers and hearers ("referential identification" as he terms it) necessarily requires reference to things possessed of material bodies, so that "we find that material bodies play a unique and fundamental role in particular identification" (*Ibid*., p. 56). As he sees it, processes will not do as basis for particular identification because: "If one had to give the spatial dimensions of such a process, say, [as] a death or a battle, one could only have the outline of the dying man or indicate the extent of the ground the battle was fought over" *Ibid*., p. 57. Strawson accordingly holds that material bodies are a necessary precondition for any setting in which objective knowledge of particulars is to be possible.

In brief outline, Strawson's argument runs essentially as follows:

1. For objective and identifiable particulars to be knowable, some items must be (1) distinguishable from other co-existents, and (2) reidentifiable over time.
2. These conditions (viz. distinguishability and reidentifiability) can only be met by material objects (i.e. particulars with material bodies).

If this line of reasoning is indeed correct, processism is untenable in metaphysics. For it is perfectly clear that any viable metaphysic must have room for identifiable particulars, and if these are to be had only on

the basis of a material-object substantialism then process metaphysics is a lost cause.

This argumentation, however, has its problems. To begin with, Strawson would have been well advised to add yet a third item, viz. (3) that individuals must not only be distinguishable and reidentifiable by a *particular* knower, but interpersonally and intersubjectively distinguishable and reidentifiable throughout a *community* of knowers. Yet even with premiss 1 strengthened in this way, premiss 2 does not hold water.

Strawson maintained that:

> The only objects which can constitute [the space-time framework essential to interpersonal communication] are those which confer upon it their own fundamental characteristics. That is to say they must be three dimensional objects with some endurance through time . . . They must collectively have enough diversity, richness, stability, and endurance to make possible just that conception of a single unitary [space-time] framework which we possess. [Page 39]

The process philosopher will have no quarrel with any of this. However, Strawson then proceeded straightaway to draw a deeply problematic conclusion:

> Of the categories of object which we recognize, only those satisfy these requirements which are, or possess, material bodies -- in the broad sense of the expression. Hence given a certain general feature of the [space-time committed] conceptual scheme which we possess, and given the character of available major categories, things which are, or possess, material bodies must be [epistemologically] basic particulars.

To its decisive detriment, Strawson's argument simply begs the question here. For all of the features that his analysis require (spatiotemporal stability and endurance, diversity, richness, interpersonal accountability, and the like) are possessed every bit as much by *physical processes* as by the things that "are or possess *material bodies*." It is not material substances (*things*) that can be distinguished and reidentified within nature's spatiotemporal framework, but occurrence-contexts (processes) as well. Processes are physically realized without being literally embodied. And the one is no less confrontable and capable of ostensive indication than the other ("that lion"; "that yawning"). Only by an act of deeply problematic fiat is Strawson able -- even within the restricted confines of his own analysis -- to advantage and prioritize material bodies over physical processes. Even Strawson's insistence that epistemically basic particulars must be identifiable by ostension holds every bit as much for instances of physical process as for particular *constrained* material bodies. (Indeed, as we shall see, it is theoretically possible to reconceptualize material bodies as complexes of physical processes, while the reverse -- the general reconceptualization of physical processes as complexes of material objects -- is just not all that plausible (the "Reism" or "Concretism" of Kotarbinski and of the later Brentano notwithstanding).)

Strawson's reasoning sets out from the quite appropriate Kantian observation that objective

distinguishably and reidentifiability requires the machinery of a spatiotemporal matrix for the emplacement of our experiential encounters with objects in a unified all-encompassing framework of coordination viz. space-time. But at this point his reasoning goes astray. For as he sees it, a spatiotemporal framework demands -- and can only be determined in terms of -- ordering relations among material objects. But there are in fact other physically "embodied" items distinct from material bodies that can serve this function equally well -- to wit, *processes*. For as long as processes have both position and duration -- as long as like a flame (rather than a sound) or a wedding ceremony (rather than something more ethical like a divorcement) -- there are items that have a sufficiently definite place and a sufficiently long lifespan to serve as coordinate markers. Processes too, in sum, can serve to define and constitute the required spatio-temporal framework.

Strawson's position is plausible only because he accepts the question-begging Process Reducibility Thesis that insists on seeing all processes in terms of the activities of things (substances). From this standpoint, all processes are owned and we are to look at them from a specifically genitive point of view: the death *of* Caesar, or the great clash *of* the armies of Napoleon and Tsar Alexander I at Borodino. But this of-indicated object-correlativity (*of* that person, *of* these two armies) takes too narrow a view of the matter. It reflects only the particular (i.e. owned) sort of processes at issue, and not their processuality as such. Where processes are more basically concerned, their object-correlativity can disappear from view.

The point is that while we can indication-identify various concrete processes *genitively* -- as per "this birth" = "the birth of Julius Ceasar" -- proceeding in terms of process-type plus substance-correlative possession, we can no less easily in dualism identify them *positionally* in terms of process-type plus location: "this birth" = "the birth at such-and-such a space-time location." And of course the referential markers that orient us in space-time need not be substantial (the town center of Greenwich) but can be processual (the pole = the place where the compass needle spins around evenly).

Accordingly, Strawson's argumentation misses its target. It is simply not the case that material objects are the indispensable basis for a framework of knowable particulars. Physical processes of a suitable sort can accomplish this essential task equally well.

7. Processes and Stability

As process ontologists see it, enduring things are never more than patterns of stability in a sea of process. Like a wave pattern in water they are simply pending configurations in a realm of change.

The very idea of a process involves trans-temporal constancies. Water evaporates. That is to say, the evaporation of water is a generic process. It has many instances, occurring alike after rainstorms in 16th century Lima and in 20th century Atlanta. Any and every particular process is always an instantiation of a general pattern. One just simply cannot identify a process that fails to be of a (processual) *type* and which, in consequence, is not -- at that level of abstraction -- capable of repetition. And so the concreta of history, viewed in an epistemic perspective, can in fact manage to transcend their space-time settings to instantiate general patterns. Although their manifestations are inevitably temporal and concrete, those

processes themselves can be atemporal and generic.

And of course different concrete instances of a process can produce products of exactly the same generic type. Different factories can and often do produce the same model of car, different cooks can and do produce the same variety of soup. And this is strikingly so when the product happens to be information: different presses can print the same text, different respondents can give the same answer to the same question, different mouths can utter the same sentence, different minds can entertain the same idea.

The point is that in the realm of informational abstractness products can escape the limitations of their (invariably relativized) productive origins. The historical relativization of the production *process* to a particular historico-cultural context -- the fact that the thinking or the assertion of a truth is so relativized -- of itself does nothing to limit the *product* (the truth that is so thought or asserted) to a historico-cultural context. Once produced, it is generally available -- and (insofar as abstract) will be cross-temporally accessible via its exemplifications and manifestations at different times and places.

Some sorts of things exist out of space but not time -- one's ownership of a piece of jewelry, for example, or one's right to exercise an option to purchase a tract of land. Other sorts of things exist neither in space nor in time -- numbers, facts, and generalized relationships for example. (The Eiffel Tower was erected in Paris in the 19th century, but the fact that Julius Caesar did not realize this is something that has no spatiotemporal emplacement.) And information is like that. The things that information may be about may be spatiotemporal, as will be the speech or writing by which the information is conveyed from one person to another. But the information itself is altogether nonspatiotemporal. It simply lies in the nature of certain sorts of things, information included, not to be located in space and time -- to be "abstract."

Admittedly, when we are viewing something, the only views we can possibly obtain are views from somewhere (and from view-points belonging to us and not to God). But when the viewing is done with the eyes of the mind, and its object is the realm of information rather than the realm of physical reality then what the view is a view of is something ahistorical. For information as such exists outside of history even though our acquiring it is invariably an historical transaction. We must avoid the category mistake of confusing process with product here: of conflating the information that we access with the historical actions and events of our accessing it.

Of course we have no way to get to the abstract (the belief) save via the historical (the believing). But what we achieve (the product) is something of a nature different and status distinct from the mode of its realization (the process). When we engage ourselves in intellectual processes that carry us into the informational domain we impel ourselves from history into an ahistorical sphere. The same idea (the same thought-process, the same belief) is accessible to people at different times and places. Were it not so, communication would be altogether impossible.

The overall situation in matters of abstraction is triadic (to use the term favored by C. S. Peirce). There are: (i) the various and sundry concrete green things; (ii) the abstract property at issue (viz., the property or characteristic of being green); and (iii) the mediative conception or idea of greenness which is the thought-instrumentalility through which that abstract property comes to be imputed to those concrete

items that putatively manifest it. The medieval metaphysical dispute between nominalism, conceptualism, and platonism needs to be resolved *conjunctively*: all three are needed: a nominalism is required for concrete particulars, a conceptualism for particular-applicative concepts, and a platonism for abstractions (e.g., in prime mathematics). The situation is not one of either/or; we must endorse all those doctrinal positions -- each in its own place.

Yet how can temporalized thought deal in timeless information? How is it that particularized episodic thought can make episode-abstractive generalizations? The long and short of it is that that’s just how thought works. To puzzle about this is like puzzling about any of the world’s brute facts. And once those realities are taken in stride the problem has been left behind. One might as well ask "How is it that money can be used to buy things? or that words can be used for speaking?" No matter how much we may wonder at the phenomena we have to accept them as part of the world’s realities.

There indeed are fundamental problems that lie in the background here: how standardized exchange is possible or how verbal communication is possible. But once such fundamental background issues are resolved, the original question is dissolved as such: something that is not a medium of exchange would not be called *money*, nor would something that could not play a generalized role in verbal or written communication be called a *word*. Even so something would not be called thought if it could not function abstractly to convey general information transcending the episodic occurrences at issue.

8. Quantum Issues

As Whitehead’s own reaction shows, the rise of the quantum theory put money in process philosopher’s bank account. The classical conception of an atom was predicated on the principle that "by definition, atoms cannot be cut up or broken into smaller parts," so that "atom-splitting" was, from the traditional point of view, simply a *contradiction in terms*. Here the demise of classical atomism brought on by the dematerialization of physical matter in the wake of the quantum theory did much to bring aid and comfort to a process-oriented metaphysics. For quantum theory taught that, at the microlevel, what was usually deemed a physical *thing*, a stably perduring object, is itself no more than a statistical pattern -- a stability wave in a surging sea of process. Those so-called enduring "things" come about through the emergence of stabilities in statistical fluctuations.

The quantum view of the world is inherently probabilistic -- indeed it has trouble coming to terms with concrete definiteness (with the "collapse of the wave packet" problem). And this too is congenial to processists, seeing that process philosophy rejects a pervasive determinism of law-compulsion. Processists see the laws of nature as imposed from below rather than above -- as servants rather than masters of the world’s existents.

Twentieth century physics has thus turned the tables on classical atomism. Instead of very small *things* (atoms) combining to produce standard processes (windstorms and such), modern physics envisions very small processes (quantum phenomena) combining in their *modus operandi* to produce standard things (ordinary macro-objects). The quantum view of reality has accordingly led to the unravelling of that

classical atomism that has, from the start, been paradigmatic for substance metaphysics.

Process metaphysics envisions a limit to determinism that makes room for creative spontaneity and novelty in the world (be it by way of random mutations with naturalistic processists or purposeful innovation with those who incline to a theologically teleological position).

Moreover, process philosophers have reason to favor quantum physics over relativistic physics. For relativity sees space time as a block that encompasses all real events concurrently, leaving the time differentiation of earlier-later to be supplied from the subjective resources of observers relative to their own mode of emplacement within the grand scheme of things. Special relativity with its preoccupation with time-invariant relationships in effect suppresses time as a factor in physical reality and relegates it to the penumbral status of a subjective phenomenon. This serves to explain why Whitehead sought to provide a new theoretical basis to relativity theory and reconstrue space-time, as well as the conception of other physical objects, as being a construction made from "fragmentary individual experiences." Processes are not the machinations of stable things; things are the stability-patterns of variable processes. All such perspectives of modern physics at the level of fundamentals dovetail smoothly into the process approach.

9. Process Theology

The God of scholastic Christian theology, like the deity of Aristotle on whose model this conception was in part based, is an immaterial individual, located outside of time -- entirely external to the realm of change and process. By contrast, process theologians, however much they may disagree on other matters, take the radical (but surely not heretical) step of according God an active role also *within* the natural world's spatio-temporal frame. They envision a foothold for God within the overall processual order of the reality that is supposed to be his creation. After all, active participation in the world's processual commerce need not necessarily make God into a physical or material object. (While the world indeed contains various physical processes like the evolution of galaxies, it also contains immaterial processes such as the diffusion of knowledge or the emergence of order.)

For process theology, then, God does *not* constitute part of the world's making of physical processes, but nevertheless in some fashion or other *participates* in it. Clearly no ready analogy-model for this mode of participation (spectator, witness, judge, etc.) can begin to do full justice to the situation. But what matters first and foremost to the angle of process theology is *the fact that* God and his world are processually inter-connected -- the issue of *the manner how* is something secondary that can be left open for further reflection. So conceived, God is not exactly *of* the world of physical reality, but does indeed participate *in* it processually -- everywhere touching, affecting, and informing its operations. Thus while not emplaced in the world, the processists' God is nevertheless bound up with it in an experiential process of interaction with it. In general, process theists do not believe that God actually controls the world. The process God makes an impact persuasively, influencing but never unilaterally imposing the world's process.

Process theology accordingly invites us to think of God's relationship to the world in terms of a process

of influence like "the spread of Greek learning in medieval Islam." Greek learning did not become literally *internal* to the Islamic world, but exerted a substantial and extensive influence upon and within it. Analogously, God is not of the world but exerts and extends an all-pervasive influence upon and within it. After all, processes need not themselves be spatial to have an impact upon things in space (think of a price inflation on the economy of a country.) The idea of process provides a category for conceptualizing God's relation to the world that averts many of the difficulties and perplexities of the traditional substance paradigm.

Even apart from process philosophy, various influential theologians have in recent years urged the necessity and desirability of seeing God not through the lens of unchanging stability but with reference to movement, change, development, and process. But, the process theorists among theologians want to go beyond this. For them, God is not only to be related to the world's processes in a productive manner, but must himself be regarded in terms of process -- as encompassing processuality as a salient aspect of the divine nature.

To be sure, process theologians differ among themselves in various matters of emphasis. Whitehead sees God in cosmological terms as an "actual occasion" functioning within nature, reflective of "the eternal urge of desire" that works "strongly and quietly by love," to guide the course of things within the world into "the creative advance into novelty." For Hartshorne, by contrast, God is less an active force within the world's processual commerce than an intelligent being or mind that interacts with it. His God is less a force of some sort than a personal being who interacts with the other mind-endowed agents through personal contact and love. Hartshorne wants neither to separate God from the world too sharply nor yet to have him be pantheistically immanent in nature. He views God as an intelligent world-separated being who participates experientially in everything that occurs in nature and resonates with it in experiential participation.

Such differences of approach, however, are only of secondary importance. The crucial fact is that the stratagem of conceiving of God in terms of a *process* that is at work in and beyond the world makes it possible to overcome a whole host of substance-geared difficulties at one blow. For it now becomes far easier to understand how God can be and be operative. To be sure, the processual view of God involves a recourse to processes of a very special kind. But extraordinary (or even supra-natural) *processes* pose far fewer difficulties than extraordinary (let alone supra-natural) *substances*, seeing that process is an inherently more flexible conception. After all, many sorts of processes are in their own way unique -- or, at any rate, radically different from all others. Clearly, processes like the creation of a world or the inauguration of its lawful order are by their very nature bound to be unusual, but much the same can be said of any particular type of process. Moreover, through its recourse to the idea of a mega-process that embraces and encompasses a variety of subordinate processes, process theology is able to provide a conceptual rationale for reconciling the idea of an all-pervasive and omnitemporal mode of reality with that of a manifold of finitely temporalized constituents.

The processist view of nature as a spatiotemporal whole constituting one vast, all-embracing cosmic process unfolding under the directive aegis of a benign intelligence is in various ways in harmony with the Judeo-Christian view of things. For this tradition has always seen God as active within the historical

process which, in consequence, represents not only a causal but also a purposive order. After all, the only sort of God who can have meaning and significance for us is one who stands in some active interrelationship with ourselves and our world. (Think here of the Nicene creed's phraseology: "the maker of all things … who for us men and for our salvation …".) But of course such an "active interrelationship" is a matter of the processes that constitute the participation and entry of the divine into the world's scheme of things -- and conversely.

And of course not only is it feasible and potentially constructive for the relation of God to the world and its creatures to be conceived of in terms of processes, but it is so also with the relationship of people to God. Here too process theology sees such a relationship as thoroughly processual because it rests on a potentially interactive communion established in contemplation, worship, prayer, etc.

In particular, for processists there is little difficulty in conceiving God as a *person*. For once we have an account of personhood in general in process terms as a systemic complex of characteristic activities, it is no longer all that strange to see God in these terms as well. If we processify the human person, then we can more readily conceive of the divine person as the focal source of a creative intelligence that engenders and sustains the world and endows it with law, beauty (harmony and order), value and meaning.

Then too there is the problem of the Trinity with its mystery of fitting three persons into one being or substance, which has always been a stumbling block for the substantialism of the Church Fathers. A process approach makes it possible to bypass this perplexity. For processes can interact and interpenetrate one another. With the laying of a single branch a woodsman can be building a wall, erecting a house, and extending a village. One act, many processes; one mode of activity many sorts of agency.

For process theology, then, God is active in relation to the world, and the world's people can and should be active in relation to God. People's relationship to the divine is a two-way street, providing for a benevolent God's care for the world's creatures and allowing those intelligent beings capable of realizing this to establish contact with God through prayer, worship, and spiritual communion. Process theology accordingly contemplates a wider realm of processes that embrace both the natural and the spiritual realms and interconnect God with the vast community of worshippers in one communal state of macroprocess that encompasses and gives embodiment to such a comprehensive whole.

To be sure, process theologians usually see the divine as one power among others and view God's role in relation to the world as rather diffused and indirect and limited. But this seems to be more because a novel perspective appeals to those of theologically liberal and unorthodox orientation than to the inherent demands of a process appraisal. In theory a process theology could take a more theologically conservative form than has been the case.

10. A Question of Legitimacy

From the days of the Pyrrhonian sceptics of antiquity we are told again and again throughout the history

of philosophy that speculative systematization is inappropriate -- that such knowledge as we humans can actually obtain is limited to the realm of everyday life and/or its precisification through science. Repeated in every era, this stricture is also rejected by many within each. The impetus for big-picture understanding, for a coherent, and panoramic view of things that puts the variegated bits and pieces together, represents an irrepressible demand of the human intellect as a possession of "the rational animal." And process metaphysics affords one of the most promising and serious options for accommodating this demand.

11. Institutionalization

Process thought constitutes one (albeit only one) very prominent sector of the active philosophical scene in the USA at the present time. Apart from the proliferation of books and articles on the topic, it has achieved considerable institutionalization during the years after World War II. Indications of this phenomenon include the formation of the Society for Process Studies, as well as the prominence of process philosophizing within the aegis of the Society for American Philosophy and the American Metaphysical Society. Another clear token is the journal *Process Studies*, Published by the Center for Process Studies in Claremont CA, and founded in 1971 by Lewis S. Ford and John B. Cobb, Jr., a publication that has in recent years become a major vehicle for article-length discussions in the field. Representatives of process philosophy occupy influential posts in departments of philosophy and of religious studies in many of American universities and colleges, and some half-dozen doctoral dissertations are produced annually in this field. American philosophy is at this historic juncture an agglomeration of different cottage industries, and process philosophy is prominent among them.

Charles Hartshorne

Charles Hartshorne is considered by many philosophers to be one of the most important philosophers of religion and metaphysicians of the twentieth century. Although Hartshorne often criticized the metaphysics of substance found in medieval philosophy, he was very much like medieval thinkers in developing a philosophy that was theocentric. Throughout his career he defended the rationality of theism and for several decades was almost alone in doing so among English-language philosophers. Hartshorne was also one of the thinkers responsible for the rediscovery of St. Anselm's ontological argument. But his most influential contribution to philosophical theism did not concern arguments for the *existence* of God, but rather was related to a theory of the *actuality* of God, i.e., *how* God exists. In traditional or classical theism, God was seen as the supreme, unchanging being, but in Hartshorne's process-based or neoclassical conception, God is seen as supreme becoming in which there is a factor of supreme being. That is, we humans become for a while, whereas God *always* becomes, Hartshorne maintains. The neoclassical view of Hartshorne has influenced the way many philosophers understand the concept of God. In fact, a small number of scholars--some philosophers and some theologians--think of him as the greatest metaphysician of the second half of the twentieth century, yet, with a few exceptions to be treated below, his work has not been very influential among analytic philosophers who are theists.

Life

Charles Hartshorne was born in the nineteenth century and lived to philosophize in the twenty-first. He was born in Kittanning, Pennsylvania (U.S.A.) on June 5, 1897. He was, like Alfred North Whitehead, the son of an Anglican minister, although many of his ancestors were Quakers. After attending Haverford College he served in World War One in France as a medic, taking a box of philosophy books with him to the front. After the war Hartshorne received his doctorate in philosophy at Harvard, and there he met Whitehead. Most of the major elements of Hartshorne's philosophy were already apparent by the time he

became familiar with Whitehead's thought, contrary to a popular misconception. From 1923-1925 a postdoctoral fellowship took him to Germany, where he had classes with both Husserl and Heidegger. But neither of these thinkers influenced his philosophy as much as C.S. Peirce, whose collected papers he edited with Paul Weiss. In addition to many visiting appointments, Hartshorne spent his teaching career at three institutions. From 1928-1955 he taught at the University of Chicago, where he was a dominant intellectual force in the School of Divinity, despite the fact that he was housed in the Philosophy Department, where he was not nearly as influential. He was at Emory University from 1955 until 1962, when he moved to the University of Texas at Austin. Hartshorne eventually became a long-term emeritus professor at Austin and lived there until his death on October 9, 2000. His wife, Dorothy, was as colorful as her husband and was mentioned often in his writings. Hartshorne never owned an automobile, nor did he smoke or drink alcohol or caffeine; he had a passion for birdsong and became an internationally known expert in the field.

Method

Three primary methodological devices or procedures are at work in Hartshorne's metaphysics. First, he very often uses a systematic exhaustion of theoretical options--or the development of position matrices, sometimes containing thirty-two alternatives(!)--in considering philosophical problems. This procedure is evident throughout his philosophy, but it is most apparent in his various treatments of the ontological argument. To take another example, he thinks it important to notice that regarding the mind-body problem there are three options available to us, not two, as is usually assumed: some form of dualism, some form of the materialist view that psyche is reducible to body, *and* some form of the panpsychist (or, as he terms it, psychicalist) view that body is in some way reducible to psyche if all concrete singulars (e.g., cells or electrons) in some way show signs of self-motion or activity. More recently, Thomas Nagel considers this third option, but Hartshorne actually defends it.

Second, Hartshorne frequently uses the history of philosophy to see which of the logically possible options made available by position matrices have been defended before so as to avail ourselves of the insights of others in the effort to examine in detail the consistency of these positions and to assess their consequences. Nonetheless, those logically possible options that have not historically found support should be analyzed both in terms of internal consistency and practical ramifications. It should be noted that Hartshorne's use of the history of philosophy often involves lesser known views of famous thinkers (like Plato's belief in God as the soul for the body of the whole natural world, or Leibniz's defense of panpsychism) as well as the thought of lesser known thinkers (such as Faustus Socinus, Nicholas Berdyaev or Jules Lecquier).

Third, after a careful reading of the history of philosophy has facilitated the conceptual and pragmatic examination of all the available options made explicit by a position matrix, the (Greek) principle of moderation is used by Hartshorne as a guide to negotiate the way between extreme views on either side. For example, regarding the issue of personal identity, the view of Hume (and of Bertrand Russell at one stage in his career) is that, strictly speaking, there is no personal identity in that each event in "a person's life" is externally related to the others. This is just as disastrous, Hartshorne thinks, as Leibniz's view that

all such events are internally related to the others, so that implicit in the fetus are all the experiences of the adult. (This Leibnizian view relies on the classical theistic, strong notion of omniscience, wherein God knows in minute detail and with absolute assurance what will happen in the future.) The Humean view fails to explain the continuity we experience in our lives and the Leibnizian view fails to explain the indeterminateness we experience when considering the future. The truth lies between these two extremes, Hartshorne thinks. His view of personal identity is based on a conception of time as asymmetrical in which later events in a person's life are internally related to former events, but they are externally related to those that follow, thus leading to a position that is at once partially deterministic and partially indeterministic. That is, the past supplies necessary but not sufficient conditions for human identity in the present, which always faces a partially indeterminate future.

Only the first of these methodological devices or procedures supports the widely held claim that Hartshorne is a rationalist. His overall method is a complex one that involves the other two methods or procedures, where he does borrow from the rationalists, but also from the pragmatists and the Greeks. It must be admitted, however, that Hartshorne was educated in a philosophic world still heavily influenced by late nineteenth and early twentieth century idealism.

The Existence and Actuality of God

Philosophers commonly use a metaphor that suggests that the chain of an argument, say for the existence of God, is only as strong as its weakest link. Hartshorne rejects this metaphor on Peircian grounds. He replaces it by suggesting that various arguments for the existence of God--ontological, cosmological, design, etc.--are like mutually reinforcing strands in a cable.

He argues that Hume's and Kant's criticisms of the ontological argument of St. Anselm are not directed at the strongest version of his argument found in *Proslogion*, chapter 3. Here, he thinks, there is a modal distinction implied between existing necessarily and existing contingently. Hartshorne's view is that existence alone might not be a real predicate, but existing necessarily certainly is. That is, contra Kant and others, Hartshorne believes that there are necessary truths concerning existence. To say that absolute nonexistence in some fashion exists is to contradict oneself; hence he thinks that absolute nonexistence is unintelligible. It is necessarily the case that *something* exists, he thinks, and, relying on the ontological argument, he also thinks it necessarily true that God exists.

On Hartshorne's view, metaphysics does not deal with realities beyond the physical, but rather with those features of reality that are ubiquitous or that would exist in any possible world. And he does not think that it is possible to think of a preeminent being that only existed contingently since if it did exist contingently rather than necessarily, it would not be preeminent. That is, God's existence is either impossible (positivism) or possible, and, if possible, then necessary (theism). He is assuming here that there are three alternatives for us to consider: (1) God is impossible; (2) God is possible, but may or may not exist; (3) God exists necessarily. The ontological argument shows that the second alternative makes no sense. Hence, he thinks that the prime task for the philosophical theist is to show that God is not impossible.

In addition, Hartshorne's detailed treatment of the argument from design is connected to his view of biology. It is hard to reconcile an omnipotent, classical theistic God with all of the monstrosities and chance mutations produced in nature, but the general orderliness of the natural world is just as difficult to reconcile with there being no Orderer or Persuader at all. Belief in God as omnipotent, he thinks, has three problems: (1) it is at odds with the disorderliness in nature; (2) it yields the acutest form of the theodicy problem; and (3) it conflicts with the notion from Plato's *Sophist*, defended by Hartshorne, that being *is* dynamic power (*dynamis*). An *omni*potent being would ultimately have all power over others, who would ultimately be powerless. But any being-in-becoming, according to Hartshorne, has *some* power to affect, or to be affected by, others; this power, however slight, provides counterevidence to a belief in divine omnipotence. In contrast, God is ideally powerful, on the Hartshornian view. That is, God is as powerful as it is possible to be, given the partial freedom and power of creatures.

Hartshorne's dispute with traditional or classical philosophical theism concerns not so much the *existence* of God, but rather its assumption that the *actuality* of God (i.e., *how* God exists) could be described in the same terms as the existence of God. A God who exists necessarily is not necessary or unchanging in every other respect (e.g., in terms of divine responsiveness to creaturely changes), he thinks. Although Hartshorne believes that the medieval thinkers were correct in trying to think through the logic of perfection, he also thinks that this logic has traditionally been misapplied in the effort to articulate the attributes of a being called "God," roughly defined as the greatest conceivable being. The traditional or classical theistic logic of perfection sees God as monopolar in that regarding various contrasts (permanence-change, one-many, activity-passivity, etc.) the traditional or classical philosophical theist has chosen one element in each pair as a divine attribute (the former element of each pair) and denigrated the other.

By way of contrast, Hartshorne's logic of perfection is dipolar. Within each element of these pairs there are good features that should be attributed in the preeminent sense to God (e.g., excellent permanence in the sense of steadfastness, excellent change in the sense of preeminent ability to respond to the sufferings of creatures). In each element in these pairs there are also invidious features (e.g., pigheaded stubbornness, fickleness). The task for the philosophical theist, he thinks, is to attribute the excellences of both elements of these pairs to God and to eschew the invidious aspects of both elements. However, it should be noted that *some* contrasts are not fit for dipolar analysis (e.g., good-evil) in that "good good" is a redundancy and "evil good" is a contradiction. The greatest conceivable being, he thinks, cannot be evil in any sense whatsoever.

Hartshorne does not claim to believe in two gods, nor does he wish to defend a cosmological dualism. In fact, we can see that the opposite is the case when we consider that, in addition to calling his theism *dipolar*, he refers to it as a type of *panentheism*, which literally means that all is *in* the one God by means of omniscience (as Hartshorne defines the term) and omnibenevolence. All creaturely feelings, especially feelings of suffering, are included in the divine life. God is seen by Hartshorne as the mind or soul for the whole body of the natural world (see above regarding Plato's World Soul), although he thinks of God as distinguishable from the creatures. Another way to categorize Hartshorne's theism is to see it as *neoclassical* in the sense that he relies on the classical or traditional theistic proofs for the existence of God and on the classical theistic metaphysics of being as *first steps* in the effort to think through properly

the logic of perfection. However, these efforts need to be supplemented, he thinks, by the efforts of those who see becoming as more inclusive than being. God is not outside of time, as in the Boethian view that is influential among traditional philosophical theists, but rather exists through all of time, on Hartshorne's view. On the neoclassical view, God's permanent "being" consists in steadfast benevolence exhibited through everlasting becoming.

God is omniscient, on Hartshorne's view, but "omniscience" here refers to the divine ability to know everything that is knowable: past actualities as already actualized; present realities to the extent that they are knowable according to the laws of physics (e.g., what is present epistemically may very well be the most recent past, given the speed of light); and future possibilities or probabilities *as possibilities or probabilities*. On the traditional or classical conception of omniscience, however, God has knowledge of future possibilities or probabilities as already actualized. According to Hartshorne, this is not an example of supreme knowledge, but is rather an example of ignorance of the (at least partially) indeterminate character of the future.

The asymmetrical view of time, common to process thinkers in general (e.g., Bergson, Whitehead, Hartshorne), in which the relationship between the present and the past is radically different from the relationship between the present and the future, also has implications for Hartshorne's theodicy. A plurality of partially free agents, including nonhuman ones, facing a future that is neither completely determined nor foreknown in detail, makes it not only possible, but likely, that these agents will get in each other's way, clash, and cause each other to suffer. On this view, God is the fellow sufferer who understands.

Axiology

Hartshorne views the cosmos as a "metaphysical monarchy," with God as the presiding, but not omnipotent, head, and he sees human society as a "metaphysical democracy," with each member as an equal. This makes him a liberal in politics if "liberalism" refers to the egalitarian belief that none of us is God. Although Hartshorne and Whitehead are both political liberals, Hartshorne is, despite his view of panpsychist reality as thoroughly social, more of a libertarian liberal and Whitehead more of a redistributive liberal. In axiology as well as in metaphysics/theodicy, freedom is crucial, on Hartshorne's view.

Hartshorne's panpsychism (or psychicalism) entails the belief that each active singular in nature, even those like electrons and plant cells that do not exhibit mentality, is nonetheless a center of intrinsic, and not merely instrumental, value. As a result, Hartshorne's metaphysics is meant to provide a basis for both an aesthetic appreciation of the value in nature, as well as for an environmental ethics where intrinsic and instrumental values in nature are weighed.

As a published expert on bird song, Hartshorne is the first philosopher since Aristotle to be an expert in both metaphysics and ornithology. He writes specifically of the aesthetic categories required to explain why birds sing outside of mating season and when territory is not threatened--two occasions for bird song

that are crucial to the behaviorists' account. Birds *like* to sing, he concludes.

Hartshorne's criticism of anthropocentrism is due not only to his concern for God, but also for beings-in-becoming who experience in a less sophisticated way than humans. To say that all active singulars feel--leaving out of the picture abstractions like "twoness" or insentient composites of active singulars that do not themselves feel as wholes--is not to say that they are self-conscious or that they think. As before, however, Hartshorne's axiology is ultimately theocentric in character.

Critical Evaluation

It seems fair to say that analytic philosophers in general, even analytic philosophers who are theists, have largely ignored Hartshorne's philosophy. This is in contrast to his wide influence among theologians, which is odd when it is considered that he is not a theologian and does not rely on sacred scripture or religious authority for his insights. Another oddity is the fact that Hartshorne's influence among theologians is due to the defense he offers of the *rationality* of belief in a neoclassical God.

There is one important philosopher whose work indicates the sort of debate that has occurred between Hartshorne and analytic theists, who tend to rely on traditional or classical versions of the concept of God. That is William Alston. There are two reasons why an evaluation of Hartshorne's philosophy is facilitated by a consideration of Alston's critique. First, Alston is as important a theist as any among analytic philosophers and his criticisms of Hartshorne's thought are like those of other analytic philosophers like Thomas Morris, Richard Creel, Michael Durrant, Colin Gunton, and others. And second, Alston is a former student of Hartshorne's and is thoroughly familiar with Hartshorne's arguments. Alston is a philosopher who is not scandalized by Hartshorne's panentheism, nor by his neoclassical theism. But Alston thinks that the contrast that Hartshorne draws between his neoclassical theism and the classical theism of Thomas Aquinas is too sharp.

Alston thinks that Hartshorne presents neoclassical theism and classical theism as complete packages, whereas it would be better to be able to pick and choose among individual items within these packages. Alston seeks some sort of rapprochement between Thomism and neoclassical theism, a rapprochement that Hartshorne himself would like to bring about to the extent that he is a neo*classical* thinker, but that is difficult to accomplish to the extent that he is *neo*classical.

A consideration of ten contrasting attributes will best facilitate an initial understanding of Hartshorne's view of God. Consider the first group of attributes treated by Alston.

CLASSICAL ATTRIBUTES	NEOCLASSICAL ATTRIBUTES
1. absoluteness (absence of internal relatedness)	1. relativity (God is internally related to creatures by way of knowledge of them and actions toward them)

2. pure actuality (there is no potentiality in God)	2. potentiality (not everything is actualized that is possible for God)
3. total necessity (every truth about God is necessarily true)	3. necessity and contingency (God exists necessarily, but various things are true of God contingently, e.g., God's knowledge of what is contingent)
4. absolute simplicity	4. complexity

Alston distinguishes two lines of argument regarding absoluteness and relativity, which he sees as the key contrast. Alston thinks that only one of these is successful. As indicated in the diagram above, what Hartshorne means by absoluteness is absence of internal relatedness. A relation is internal to a term of a relation just in case that term would not be exactly as it is if it were not in that relationship. Hartshorne's view is that God has internal relations to creatures by way of knowing and acting towards them.

On Alston's interpretation, Hartshorne's first line of argument is to say that if the relation of the absolute to the world really fell outside the absolute, then this relation would necessarily fall within some further and genuinely single entity that embraced both the absolute and the world and the relations between them. Thus, we must hold, according to Hartshorne, that the God-creature relation is internal to God; otherwise we will have to admit that there is something greater or more inclusive than God. Alston does not find this argument convincing because it includes the claim that God "contains" the world due to the internal relations God has with the world. Alston's view is that the entity to which a relation is internal contains the terms only in the sense that those terms enter into a description of the entity, but it does not follow from this that those terms are contained in that entity as marbles are in a box.

Divine inclusiveness, for Hartshorne, is sometimes like the inclusion of thoughts in a mind, but usually it is described as like the inclusion of cells within a living body. It is never like the inclusion of marbles in a box. The inorganic and insentient character of a box is inadequate as a model for divinity, he thinks, and divine inclusiveness is never like the inclusion of theorems in a set of axioms, as it might be for certain idealists. Divine inclusiveness in Hartshorne is *organic* inclusiveness.

Hartshorne's second argument against absoluteness fares much better, according to Alston. He agrees with Hartshorne's stance regarding the cognitive relation God has with the world; in any case of knowledge, the knowledge relation is internal to the subject, external to the object. When a human being knows something, the fact that she knows it is part of what makes her the concrete being that she is. If she recognizes a certain tree she is different from the being she might have been if she had not recognized the tree. But the tree is unaffected by her recognition. Likewise, according to Alston, one cannot maintain that God has perfect knowledge of everything knowable and still hold that God is not qualified to any degree by relations with other beings.

One might respond to Alston and Hartshorne on this point by saying that since creatures depend for their existence on God, their relations to God affect *them*, but not God. Creel seems to make this very point.

But even if beings other than God depend for their existence on God, it still remains true that if God had created a different world from the one that exists at present, then God would be somewhat different from the way God is at present: God's knowledge would have been of *that* world and not this one, according to both Alston and Hartshorne.

Alston's concessions to Hartshorne's concept of God extend to contrasts 2-4. The above argument for the internal relatedness of God (as cognitive subject) to the world presupposes that there are alternative possibilities for God, and if there are alternative possibilities for divine knowledge then this implies that there are unrealized potentialities for God. *Pure* actuality and *total* necessity cannot be defended as divine attributes, according to Alston and Hartshorne. Alston's version of Hartshorne's argument goes as follows:

> (1) (a) "God knows that W exists" entails (b) "W exists."
>
> (2) If (a) were necessary, (b) would be necessary.
>
> (3) But (b) is contingent.
>
> (4) Hence (a) is contingent.

We can totally exclude contingency from God only by denying God any knowledge of anything contingent, a step that not even traditional or classical theists wish to take. Contrast 4 must also be treated in a dipolar way in that the main support for a doctrine of pure divine simplicity is the absence of any unrealized potentialities in God.

In sum, Alston and Hartshorne agree on contrasts 1-4, except for the fact that Hartshorne's concept of divine inclusiveness, in contrast to Alston's, is organic in character.

Regarding a second group of attribues, however, Alston and other theists who are analytic philosophers diverge from Hartshorne rather significantly:

CLASSICAL ATTRIBUTES	NEOCLASSICAL ATTRIBUTES
5. creation *ex nihilo* by a free act of will; God could have refrained from creating anything	5. both God and the world of creatures exist necessarily, although the details are contingent
6. omnipotence (God has the power to do anything God wills to do that is logically consistent)	6. God has all the power one agent could have given metaphysical, in addition to logical, limitations
7. incorporeality	7. corporeality (the world is the body of God)

8. nontemporality (God does not live through a series of moments)	8. temporality (God lives through temporal succession, but everlastingly)
9. immutability (God cannot change because God is not temporally successive)	9. mutability (God is continually attaining richer syntheses of experience)
10. absolute perfection (God is eternally that than which no more perfect can be conceived)	10. relative perfection (at any moment God is more perfect than any other, but God is self-surpassing at a later stage of development)

Concerning contrast 5, Alston takes creation *ex nihilo* to be fundamental to theism because it has deep roots in religious experience. He thinks that to say that God has unrealized potentialities and contingent properties is not to say that God *must* be in relation with some world of entities other than God. Alston admits that Hartshorne legitimately points out some of the internal contradictions contained in the classical theistic version of creation *ex nihilo*, but he claims that there is no connection drawn by Hartshorne between divine creation and metaphysical principles regarding relativity, contingency, and potentiality. Alston's belief seems to be that those who accept creation *ex nihilo* are not saying that there is absolutely nothing at any stage: there is God. Rather, creation *ex nihilo* only means that there is nothing out of which God creates the universe. Here Alston seems to agree with Norman Kretzmann, Eleonore Stump, and most other theists who are analytic philosophers.

Alston's stance here is problematic for two reasons, from Hartshorne's point of view. First, although belief in *some* sort of divine creativity has deep roots in the history of religious experience, it is not clear that these roots have to tap into creation *ex nihilo*. For example, it is not clear that creation *ex nihilo* is the sort of creation described in Genesis, in that when the Bible starts with the statement that the spirit of God hovered above the waters, one gets the impression that both God and the aqueous muck had been around forever. If one believes in creation *ex nihilo*, however, as Alston does, one might nonetheless claim that creation *ex nihilo* does not necessarily mean a temporal beginning to the act of creation. But even on this hypothesis there are problems, and this would seem to be Hartshorne's second point. If Plato and Hartshorne are correct that being *is* dynamic power, then the sort of unlimited power implied by creation *ex nihilo* is impossible. Hartshorne would argue, contra Alston, that there is a connection between belief in creation *ex hyle* (as opposed to creation *ex nihilo*) and the metaphysical principle that being is dynamic power. Creation *ex nihilo*, Hartshorne thinks, is a convenient fiction invented in the first centuries B.C.E. and C.E. in order to exalt divine power, but it is not the only sort of creation that religious believers have defended, nor is it defensible if being is dynamic power.

Concerning contrast 6, Alston claims that belief in creation *ex nihilo* and belief in divine omnipotence are separate beliefs such that to argue against the former is not necessarily to argue against the latter. Hartshorne tries to do too much, he thinks, with the claim that being is power when he uses this claim to argue against divine omnipotence. According to Alston, God can have *unlimited* power, power to do anything that God wills to do, without having *all* power in that, if being is power, the creatures also have some power.

On Hartshorne's interpretation of Alston, however, God can have unlimited power, but not all power, because God delegates some power to others. Although God does not have all power, Hartshorne thinks that on Alston's view God *could* have all power. In effect, what Alston has done, according to Hartshorne, is reduce his stance regarding divine omnipotence to that regarding creation *ex nihilo* in that the claim that God could have all power is due to the prior belief that God brings everything into existence out of absolutely nothing, a belief that Alston thinks has to be the traditional one and in point of fact is intelligible. It is not quite clear to Hartshorne, however, that it is unquestionably the traditional one, nor is it clear to him that we can develop an intelligible concept of "absolutely nothing."

Hartshorne's Platonic or Bergsonian argument against creation *ex nihilo*, in simplified form, looks something like this: one can in fact imagine the nonexistence of this or that, or even of this or that class of things, a fact that gives some the confidence to (erroneously) think that this process can go on infinitely such that one could imagine a state in which there was "absolutely nothing." However, not every verbally possible statement is made conceptually cogent by even the most generous notion of "conceptual," according to Hartshorne. At the specific, ordinary, empirical level negative instances are possible, but at the generic, metaphysical level only positive instances are possible, on this view. The sheer absence of reality cannot conceivably be experienced, he thinks, for if it were experienced an existing experiencer would be presupposed.

Contrast 7 deals with divine embodiment. Alston is willing to grant that God is embodied in two senses: (1) God is aware, with maximal immediacy, of what goes on in the world; and (2) God can directly affect what happens in the world. That is, Alston defends a limited version of divine embodiment, similar to that defended by Richard Swinburne. However, Alston is sceptical regarding a stronger version of divine embodiment wherein the world exists by metaphysical necessity such that God *must* animate it. Alston is willing to accept the idea that God has a body, but *only if* having such a body is on God's terms. It seems that this weaker version of divine embodiment defended by Alston, as opposed to Hartshorne's stronger version wherein there is essential corporeality in God, stands or falls with the defense of creation *ex nihilo*. In fact, despite Alston's desire to examine each contrast individually, as opposed to Hartshorne's stark contrast between classical theistic attributes (all ten of them) and neoclassical attributes (all ten of them), he ends up linking his criticisms of Hartshorne regarding contrasts 5-7, at the very least. All three of these classical theistic attributes stand together only with a defensible version of creation *ex nihilo*.

Contrasts 8-9, concerning nontemporality and immutability, are also linked by Alston. He concedes that if God is temporal, Hartshorne has offered us the best version to date of what divine temporality and divine mutability would be like. Alston dismisses as idle the view that God could remain completely unchanged through a succession of temporal moments, but this admission still leaves us, he thinks, with the following conditional statement: "God undergoes change *if* God is in time." Alston's critique of Hartshorne's view also consists in a refusal to grant that contingency and temporality are coextensive in the way mutability and temporality are. Alston believes, contra Hartshorne, that God can be in some way contingent (that any relation in which God stands to the world might have been otherwise) and still be nontemporal.

Alston knows that the notion of a nontemporal God who is qualified by relation to temporal beings will strike Hartshorne as unintelligible. Alston's attempt to make his position intelligible rests on his own Thomistic-Whiteheadian stance, or better, on his Thomistic or Boethian interpretation of Whitehead (strange as this seems). We should not think of God as involved in process or becoming of any sort. The best temporal analogy, he thinks, for this conception is an unextended instant or an "eternal now." For Alston this does not commit one, however, as Hartshorne would allege, to a static deity frozen in immobility. On the contrary, according to Alston, God is eternally active in ways that do not require temporal succession. God's acts can be complete in an instant. Alston includes God's acts of knowledge, a stance that at least seems to conflict with one of the concessions he made to Hartshorne regarding the first group of attributes.

The Boethian-Thomistic notion of the specious present for God, on the analogue of a human being's perceiving some temporally extended stretch of a process in one temporally indivisible act, is also defended by Alston. For example, one can perceive the flight of a bee "all at once" without first perceiving the first half of the stretch of flight and then perceiving the second. One's perception can be without temporal succession even if the object of one's perception is, in fact, temporally successive. All we have to do, on Alston's view, is expand our specious present to cover all of time and we have a model for God's awareness of the world. This is a much more difficult project for Hartshorne to imagine than it is for Alston. Apparently Alston thinks that it is easy to conceptualize God "seeing" Neanderthal man (or Adam), Moses, Jesus, and Dorothy Day all at once in their immediacy. Here Alston has a view similar to that of William Mann.

But even if it were possible to have nonsuccessive *awareness* of a vast succession, which Hartshorne would deny, it is even more implausible, from Hartshorne's point of view, to claim, as does Alston, that God could have nonsuccessive *responses* to stages of that succession. It might make more sense for Alston to say "indesponses" or "presponses" rather than "responses," as Creel would urge.

It is correct of Alston to notice that there is no loss in God, but this is not incompatible with God's temporality, according to Hartshorne. There can be succession in God without there being loss or perishing due to the fact that God's inheritance of what happens in the world and God's memory are ideal. Hartshorne thinks that the future is incomplete and indeterminate for God as well as from our limited perspective. Alston, by way of contrast, wants to defend a God who is not strictly necessary in actuality, but is contingent, *despite the fact that* God does not undergo temporal change, nor is God fluent. Hartshorne's defenders, by way of contrast, think that one of the greatest virtues of process thinking is its effort to eliminate what they see as such self-contradiction in philosophical theology.

Alston's treatment of contrast 10, concerning absolute versus relative perfection, follows from what he has said regarding contrasts 8-9. Relative perfection in God, as opposed to absolute perfection, has a point only for a temporal being; hence God is absolutely perfect, according to Alston. A being that does not successively assume different states could not possibly surpass itself. Here, once again, Alston engages in linkage, thereby, at the very least, confirming Hartshorne's belief that we need both to consider the divine attributes together and to determine whether the classical theist's linkage or the neoclassical theist's linkage is more defensible. For the most past, Alston opts for classical theism. Or

more precisely, he thinks that the strongest concept of God is acquired when we take a modified version of the neoclassical attributes in contrasts 1-4 and combine them with the classical attributes in contrasts 5-10.

This rapproachement in Alston between classical theism and neoclassical theism is a step beyond James Ross's belief that these are two competing descriptions of God at an impasse. Hartshorne seems to agree with Ross. Neoclassical, dipolar theism *already* includes the best insights of classical theism, he thinks.

From Hartshorne's point of view the linkage of attributes *within* the first group and *within* the second group needs to be corrected by a greater concern for reticulating the attributes in these two groups. He thinks that an explanation is needed regarding how Alston can be committed to both monopolar and dipolar theism. For example, Alston ends up defending the view that God is changed by the objects God knows (pace the neoclassical, dipolar attributes), but these are not changes that occur in time (pace the classical, monopolar attributes). It is one thing, Hartshorne thinks, to say that God exists in a nontemporal specious present, and it is another to say that God is changed by temporal beings in a nontemporal specious present. The former view is at least problematic, he thinks, and the latter seems to be part of the traditional classical theistic view wherein, from a Hartshornian perspective, inconsistency goes in the guise of mystery.

Saint Anselm

Saint Anselm of Canterbury (1033-1109) was the outstanding Christian philosopher and theologian of the eleventh century. He is best known for the celebrated "ontological argument" for the existence of God in chapter two of the *Proslogion*, but his contributions to philosophical theology (and indeed to philosophy more generally) go well beyond the ontological argument. In what follows I examine Anselm's theistic proofs, his conception of the divine nature, and his account of human freedom, sin, and redemption.

Life and Works

Anselm was born in 1033 near Aosta, in those days a Burgundian town on the frontier with Lombardy. Little is known of his early life. He left home at twenty-three, and after three years of apparently aimless travelling through Burgundy and France, he came to Normandy in 1059. Once he was in Normandy, Anselm's interest was captured by the Benedictine abbey at Bec, whose famous school was under the direction of Lanfranc, the abbey's prior. Lanfranc was a scholar and teacher of wide reputation, and under his leadership the school at Bec had become an important center of learning, especially in dialectic. In 1060 Anselm entered the abbey as a novice. His intellectual and spiritual gifts brought him rapid advancement, and when Lanfranc was appointed abbot of Caen in 1063, Anselm was elected to succeed him as prior. He was elected abbot in 1078 upon the death of Herluin, the founder and first abbot of Bec. Under Anselm's leadership the reputation of Bec as an intellectual center grew, and Anselm managed to write a good deal of philosophy and theology in addition to his teaching, administrative duties, and extensive correspondence as an adviser and counsellor to rulers and nobles all over Europe and beyond. His works while at Bec include the *Monologion* (1076), the *Proslogion* (1077-78), and his four

philosophical dialogues: *De grammatico*, *De veritate*, and *De libertate arbitrii* (1080-85), and *De casu diaboli* (1085-1090).

In 1093 Anselm was enthroned as Archbishop of Canterbury. The previous Archbishop, Anselm's old master Lanfranc, had died four years earlier, but the King, William Rufus, had left the see vacant in order to plunder the archiepiscopal revenues. Anselm was understandably reluctant to undertake the primacy of the Church of England under a ruler as ruthless and venal as William, and his tenure as Archbishop proved to be as turbulent and vexatious as he must have feared. William was intent on maintaining royal authority over ecclesiastical affairs and would not be dictated to by Archbishop or Pope or anyone else. So, for example, when Anselm went to Rome in 1097 without the King's permission, William would not allow him to return. When William was killed in 1100, his successor, Henry I, invited Anselm to return to his see. But Henry was as intent as William had been on maintaining royal jurisdiction over the Church, and Anselm found himself in exile again from 1103 to 1107. Despite these distractions and troubles, Anselm continued to write. His works as Archbishop of Canterbury include the *Epistola de Incarnatione Verbi* (1092-94), *Cur Deus Homo* (1094-98), *De conceptu virginali* (1099-1100), *De processione Spiritus Sancti* (1102), the *Epistola de sacrificio azymi et fermentati* (1106-7), *De sacramentis ecclesiae* (1106-7), and *De concordia* (1107-8). Anselm died on 21 April 1109. He was canonized in 1494 and named a Doctor of the Church in 1720.

The Theistic Proofs

"Faith Seeking Understanding": The character and purpose of Anselm's theistic proofs

Anselm's motto is "faith seeking understanding" (*fides quaerens intellectum*). This motto lends itself to at least two misunderstandings. First, many philosophers have taken it to mean that Anselm hopes to *replace* faith with understanding. If one takes 'faith' to mean roughly 'belief on the basis of testimony' and 'understanding' to mean 'belief on the basis of philosophical insight', one is likely to regard faith as an epistemically substandard position; any self-respecting philosopher would surely want to leave faith behind as quickly as possible. The theistic proofs are then interpreted as the means by which we come to have philosophical insight into things we previously believed solely on testimony. But as I have argued elsewhere (Williams 1996, xiii-xiv), Anselm is not hoping to replace faith with understanding. Faith for Anselm is more a volitional state than an epistemic state: it is love for God and a drive to act as God wills. In fact, Anselm describes the sort of faith that "merely believes what it ought to believe" as "dead" (*M* 78). (For the abbreviations used in references, see the Bibliography below.) So "faith seeking understanding" means something like "an active love of God seeking a deeper knowledge of God."

Other philosophers have noted that "faith seeking understanding" begins with "faith," not with doubt or suspension of belief. Hence, they argue, the theistic arguments proposed by faith seeking understanding are not really meant to convince unbelievers; they are intended solely for the edification of those who already believe. This too is a misreading of Anselm's motto. For although the theistic proofs are borne of

an active love of God seeking a deeper knowledge of the beloved, the proofs themselves are intended to be convincing even to unbelievers. Thus Anselm opens the *Monologion* with these words:

> If anyone does not know, either because he has not heard or because he does not believe, that there is one nature, supreme among all existing things, who alone is self-sufficient in his eternal happiness, who through his omnipotent goodness grants and brings it about that all other things exist or have any sort of well-being, and a great many other things that we must believe about God or his creation, I think he could at least convince himself of most of these things by reason alone, if he is even moderately intelligent. (*M* 1)

And in the *Proslogion* Anselm sets out to convince "the fool," that is, the person who "has said in his heart, ‘There is no God’ " (Psalm 14:1; 53:1).

The arguments of the *Monologion*

Having clarified what Anselm takes himself to be doing in his theistic proofs, we can now examine the proofs themselves. In the first chapter of the *Monologion* Anselm argues that there must be some one thing that is supremely good, through which all good things have their goodness. For whenever we say that different things are *F* in different degrees, we must understand them as being *F* through *F*-ness; *F*-ness itself is the same in each of them. Thus, for example, all more or less just things "must be more or less just through justice, which is not different in diverse things" (*M* 1). Now we speak of things as being *good* in different degrees. So by the principle just stated, these things must be good through some one thing. Clearly that thing is itself a great good, since it is the source of the goodness of all other things. Moreover, that thing is good *through itself*; after all, if all good things are good through that thing, it follows trivially that that thing, being good, is good through itself. Things that are good through another (i.e., things whose goodness derives from something other than themselves) cannot be equal to or greater than the good thing that is good through itself, and so that which is good through itself is *supremely* good. Anselm concludes, "Now that which is supremely good is also supremely great. There is, therefore, some one thing that is supremely good and supremely great--in other words, supreme among all existing things" (*M* 1). In chapter 2 he applies the principle of chapter 1 in order to derive (again) the conclusion that there is something supremely great.

In chapter 3 Anselm argues that all existing things exist through some one thing. Every existing thing, he begins, exists either through something or through nothing. But of course nothing exists through nothing, so every existing thing exists through something. There is, then, either some one thing through which all existing things exist, or there is more than one such thing. If there is more than one, either (i) they all exist through some one thing, or (ii) each of them exists through itself, or (iii) they exist through each other. (iii) makes no sense. If (ii) is true, then "there is surely some one power or nature of self-existing that they have in order to exist through themselves" (*M* 3); in that case, "all things exist more truly through that one thing than through the several things that cannot exist without that one thing" (*M* 3). So (ii) collapses into (i), and there is some one thing through which all things exist. That one thing, of course, exists through itself, and so it is greater than all the other things. It is therefore "best and greatest

and supreme among all existing things" (*M* 3).

In chapter 4 Anselm begins with the premise that things "are not all of equal dignity; rather, some of them are on different and unequal levels" (*M* 4). For example, a horse is better than wood, and a human being is more excellent than a horse. Now it is absurd to think that there is no limit to how high these levels can go, "so that there is no level so high that an even higher level cannot be found" (*M* 4). The only question is how many beings occupy that highest level of all. Is there just one, or are there more than one? Suppose there are more than one. By hypothesis, they must all be equals. If they are equals, they are equals through the same thing. That thing is either identical with them or distinct from them. If it is identical with them, then they are not in fact many, but one, since they are all identical with some one thing. On the other hand, if that thing is distinct from them, then they do not occupy the highest level after all. Instead, that thing is greater than they are. Either way, there can be only one being occupying the highest level of all.

Anselm concludes the first four chapters by summarizing his results:

> Therefore, there is a certain nature or substance or essence who through himself is good and great and through himself is what he is; through whom exists whatever truly is good or great or anything at all; and who is the supreme good, the supreme great thing, the supreme being or subsistent, that is, supreme among all existing things. (*M* 4)

He then goes on (in chapters 5-65) to derive the attributes that must belong to the being who fits this description. But before we look at Anselm's understanding of the divine attributes, we should turn to the famous proof in the *Proslogion*.

The arguments of the *Proslogion*

Looking back on the sixty-five chapters of complicated argument in the *Monologion*, Anselm found himself wishing for a simpler way to establish all the conclusions he wanted to prove. As he tells us in the preface to the *Proslogion*, he wanted to find

> a single argument that needed nothing but itself alone for proof, that would by itself be enough to show that God really exists; that he is the supreme good, who depends on nothing else, but on whom all things depend for their being and for their well-being; and whatever we believe about the divine nature. (*P*, preface)

That "single argument" is the one that appears in chapter 2 of the *Proslogion*. (We owe the curiously unhelpful name "ontological argument" to Kant. The medievals simply called it "that argument of Anselm's" [*argumentum Anselmi*].)

The argument goes like this. God is "that than which nothing greater can be thought"; in other words, he is a being so great, so full of metaphysical oomph, that one cannot so much as conceive of a being who

would be greater than God. The Psalmist, however, tells us that "The fool has said in his heart, 'There is no God' " (Psalm 14:1; 53:1). Is it possible to convince the fool that he is wrong? It is. All we need is the definition of God as "that than which nothing greater can be thought." The fool does at least understand that definition. But whatever is understood exists in the understanding, just as the plan of a painting he has yet to execute already exists in the understanding of the painter. So that than which nothing greater can be thought exists in the understanding. But if it exists in the understanding, it must also exist in reality. For it is greater to exist in reality than to exist merely in the understanding. Therefore, if that than which nothing greater can be thought existed only in the understanding, it would be possible to think of something greater than it (namely, that same being existing in reality as well). It follows, then, that if that than which nothing greater can be thought existed only in the understanding, it would not be that than which nothing greater can be thought; and that, obviously, is a contradiction. So that than which nothing greater can be thought must exist in reality, not merely in the understanding.

Versions of this argument have been defended and criticized by a succession of philosophers from Anselm's time through the present day (see ontological arguments). Our concern here is with Anselm's own version, the criticism he encountered, and his response to that criticism. A monk named Gaunilo wrote a "Reply on Behalf of the Fool," contending that Anselm's argument gave the Psalmist's fool no good reason at all to believe that that than which nothing greater can be thought exists in reality. Gaunilo's most famous objection is an argument intended to be exactly parallel to Anselm's that generates an obviously absurd conclusion. Gaunilo proposes that instead of "that than which nothing greater can be thought" we consider "that island than which no greater can be thought." We understand what that expression means, so (following Anselm's reasoning) the greatest conceivable island exists in our understanding. But (again following Anselm's reasoning) that island must exist in reality as well; for if it did not, we could imagine a greater island--namely, one that existed in reality--and the greatest conceivable island would not be the greatest conceivable island after all. Surely, though, it is absurd to suppose that the greatest conceivable island actually exists in reality. Gaunilo concludes that Anselm's reasoning is fallacious.

In order to defend himself against Gaunilo's criticism, Anselm would have to show why Gaunilo's argument about the island is not in fact analogous to his own argument about that than which nothing greater can be thought. Surprisingly, he never does this. His long-winded and indeed somewhat intemperate "Reply to Gaunilo" *asserts* more than once that the island example fails, but he never explains *why* it fails. The usual reply given on Anselm's behalf (and indeed often attributed to Anselm himself) is that the notion of a greatest conceivable island is incoherent; however great an island might be, one could always conceive of a greater. This is a lame response, since it is open to Gaunilo to say exactly the same thing about the greatest conceivable *being*; it is therefore no wonder that Anselm did not say anything of the sort. (For a reading of the argument that endorses a response of this sort, see Klima 2000.) Indeed, Nicholas Wolterstorff argues convincingly that Anselm

> realized the 'tellingness' of [Gaunilo's] points. . . . The sign of his realization, however, is not concession; Anselm does not concede. The sign is rather bluster. . . . Anselm's glittering genius has made many reluctant to concede that Gaunilo made any telling points against him; his saintly reputation makes us all reluctant to concede that he concealed

when he should have conceded. (Wolterstorff 1993, 87)

The Divine Nature

Proving the divine attributes

Recall that Anselm's intention in the *Proslogion* was to offer a single argument that would establish not only the existence of God but also the various attributes that Christians believe God possesses. If the argument of chapter 2 proved only the existence of God, leaving the divine attributes to be established piecemeal as in the *Monologion*, Anselm would consider the *Proslogion* a failure. But in fact the concept of that than which nothing greater can be thought turns out to be marvelously fertile. God must, for example, be omnipotent. For if he were not, we could conceive of a being greater than he. But God is that than which no greater can be thought, so he must be omnipotent. Similarly, God must be just, self-existent, invulnerable to suffering, merciful, timelessly eternal, non-physical, non-composite, and so forth. For if he lacked any of these qualities, he would be less than the greatest conceivable being, which is impossible.

The ontological argument thus works as a sort of divine-attribute-generating machine. Admittedly, though, the appearance of theoretical simplicity is somewhat misleading. The "single argument" produces conclusions about the divine attributes only when conjoined with certain beliefs about what is greater or better. That is, the ontological argument tells us that God has whatever characteristics it is better or greater to have than to lack, but it does not tell us which characteristics those are. We must have some independent way of identifying them before we can plug them into the ontological argument and generate a full-blown conception of the divine nature. Anselm identifies these characteristics in part by appeal to intuitions about value, in part by independent argument. To illustrate Anselm's method, I shall examine his discussions of God's impassibility, timelessness, and simplicity.

According to the doctrine of divine impassibility, God is invulnerable to suffering. Nothing can act upon him; he is in no way passive. He therefore does not feel emotions, since emotions are states that one undergoes rather than actions one performs. Anselm does not find it necessary to *argue* that impassibility is a perfection; he thinks it is perfectly obvious that "it is better to be . . . impassible than not" (*P* 6), just as it is perfectly obvious that it is better to be just than not-just. His intuitions about value are shaped by the Platonic-Augustinian tradition of which he was a part. Augustine took from the Platonists the idea that the really real things, the greatest and best of beings, are stable, uniform, and unchanging. He says in *On Free Choice of the Will* 2.10, "And you surely could not deny that the uncorrupted is better than the corrupt, the eternal than the temporal, and the invulnerable than the vulnerable"; his interlocutor replies simply, "Could anyone?" Through Augustine (and others) these ideas, and the conception of God to which they naturally lead, became the common view of Christian theologians for well over a millennium. For Anselm, then, it is obvious that a being who is in no way passive, who cannot experience anything of which he is not himself the origin, is better and greater than any being who can be acted upon by something outside himself. So God, being that than which nothing greater can be thought, is wholly

active; he is impassible.

Notice that Augustine also found it obvious that the eternal is better than the temporal. According to Plato's *Timaeus*, time is a "moving image of eternity" (37d). It is a shifting and shadowy reflection of the really real. As later Platonists, including Augustine, develop this idea, temporal beings have their existence piecemeal; they exist only in this tiny sliver of a now, which is constantly flowing away from them and passing into nothingness. An eternal being, by contrast, is (to use my earlier description) stable, uniform, and unchanging. What it has, it always has; what it is, it always is; what it does, it always does. So it seems intuitively obvious to Anselm that if God is to be that than which nothing greater can be thought, he must be eternal. That is, he must be not merely everlasting, but outside time altogether.

In addition to this strong intuitive consideration, Anselm at least hints at a further argument for the claim that it is better to be eternal than temporal. He opens chapter 13 of the *Proslogion* by observing, "Everything that is at all enclosed in a place or time is less than that which is subject to no law of place or time" (*P* 13). His idea seems to be that if God were in time (or in a place), he would be bound by certain constraints inherent in the nature of time (or place). His discussion in *Monologion* 22 makes the problem clear:

> This, then, is the condition of place and time: whatever is enclosed within their boundaries does not escape being characterized by parts, whether the sort of parts its place receives with respect to size, or the sort its time suffers with respect to duration; nor can it in any way be contained as a whole all at once by different places or times. By contrast, if something is in no way constrained by confinement in a place or time, no law of places or times forces it into a multiplicity of parts or prevents it from being present as a whole all at once in several places or times. (*M* 22)

So at least part of the reason for holding that God is timeless is that the nature of time would impose constraints upon God, and of course it is better to be subject to no external constraints.

The other part of the reason, though, is that if God were in place or time he would have *parts*. But what is so bad about having parts? This question brings us naturally to the doctrine of divine simplicity, which is simply the doctrine that God has no parts of any kind. Even for an Augustinian like Anselm, the claim that it is better to lack parts than to have them is less than intuitively compelling, so Anselm offers further arguments for that claim. In the *Proslogion* he argues that "whatever is composed of parts is not completely one. It is in some sense a plurality and not identical with itself, and it can be broken up either in fact or at least in the understanding" (*P* 18). The argument in the *Monologion* goes somewhat differently. "Every composite," Anselm argues, "needs the things of which it is composed if it is to subsist, and it owes its existence to them, since whatever it is, it is through them, whereas those things are not through it what they are" (*M* 17). The argument in the *Proslogion*, then, seeks to relate simplicity to the intuitive considerations that identify what is greatest and best with what is stable, uniform, and unchanging; the argument in the *Monologion*, by contrast, seeks to show that simplicity is necessary if God is to be--as the theistic proofs have already established--the ultimate source of his own goodness and

existence.

The consistency of the divine attributes

Anselm's success in generating a whole host of divine attributes through the ontological argument does present him with a problem. He must show that the attributes are consistent with each other--in other words, that is possible for one and the same being to have all of them. For example, there seems at first glance to be a conflict between justice and omnipotence. If God is perfectly just, he cannot lie. But if God is omnipotent, how can there be something he cannot do? Anselm's solution is to explain that omnipotence does not mean the ability to do everything; instead, it means the possession of unlimited power. Now the so-called "ability" or "power" to lie is not really a power at all; it is a kind of weakness. Being omnipotent, God has no weakness. So it turns out that omnipotence actually *entails* the inability to lie.

Another apparent contradiction is between God's mercy and his justice. If God is just, he will surely punish the wicked as they deserve. But because he is merciful, he spares the wicked. Anselm tries to resolve this apparent contradiction by appeal to God's goodness. It is better, he says, for God "to be good both to the good and to the wicked than to be good only to the good, and it is better to be good to the wicked both in punishing and in sparing them than to be good only in punishing them" (*P* 9). So God's supreme goodness requires that he be both just and merciful. But Anselm is not content to resolve the apparent tension between justice and mercy by appealing to some other attribute, goodness, that entails both justice and mercy; he goes on to argue that justice itself requires mercy. Justice to sinners obviously requires that God punish them; but God's justice *to himself* requires that he exercise his supreme goodness in sparing the wicked. "Thus," Anselm says to God, "in saving us whom you might justly destroy . . . you are just, not because you give us our due, but because you do what is fitting for you who are supremely good" (*P* 10). In spite of these arguments, Anselm acknowledges that there is a residue of mystery here:

> Thus your mercy is born of your justice, since it is just for you to be so good that you are good even in sparing the wicked. And perhaps this is why the one who is supremely just can will good things for the wicked. But even if one can somehow grasp why you can will to save the wicked, certainly no reasoning can comprehend why, from those who are alike in wickedness, you save some rather than others through your supreme goodness and condemn some rather than others through your supreme justice. (*P* 11)

In other words, the philosopher can trace the conceptual relations among goodness, justice, and mercy, and show that God not only can but must have all three; but no human reasoning can hope to show why God displays his justice and mercy in precisely the ways in which he does.

Freedom, Sin, and Redemption

Truth in statements and in the will

In *On Freedom of Choice* (*De libertate arbitrii*) Anselm defines freedom of choice as "the power to preserve rectitude of will for its own sake" (*DLA* 3). He explores the notion of rectitude of will most thoroughly in *On Truth* (*De veritate*), so in order to understand the definition of freedom of choice, we must look first at Anselm's discussion of truth. Truth is a much broader notion for Anselm than for us; he speaks of truth not only in statements and opinions but also in the will, actions, the senses, and even the essences of things. In every case, he argues, truth consists in correctness or "rectitude." Rectitude, in turn, is understood teleologically; a thing is correct whenever it is or does whatever it ought, or was designed, to be or do. For example, statements are made for the purpose of "signifying that what-is is" (*DV* 2). A statement therefore is correct (has rectitude) when, and only when, it signifies that what-is is. So Anselm holds a correspondence theory of truth, but it is a somewhat unusual correspondence theory. Statements are true when they correspond to reality, but only because corresponding to reality is what statements are *for*. That is, statements (like anything else) are true when they do what they were designed to do; and what they were designed to do, as it happens, is to correspond to reality.

Truth in the will also turns out to be rectitude, again understood teleologically. Rectitude of will means willing what one ought to will or (in other words) willing that for the sake of which one was given a will. So, just as the truth or rectitude of a statement is the statement's doing what statements were made to do, the truth or rectitude of a will is the will's doing what wills were made to do. In *DV* 12 Anselm connects rectitude of will to both justice and moral evaluation. In a broad sense of ‘just’, whatever is as it ought to be is just. Thus, an animal is just when it blindly follows its appetites, because that is what animals were meant to do. But in the narrower sense of ‘just’, in which justice is what deserves moral approval and injustice is what deserves reproach, justice is best defined as "rectitude of will preserved for its own sake" (*DV* 12). Such rectitude requires that agents perceive the rectitude of their actions and will them for the sake of that rectitude. Anselm takes the second requirement to exclude both coercion and "being bribed by an extraneous reward" (*DV* 12). For an agent who is coerced into doing what is right is not willing rectitude for its own sake; and similarly, an agent who must be bribed to do what is right is willing rectitude for the sake of the bribe, not for the sake of rectitude.

Since, as we have already seen, Anselm will define freedom as "the power to preserve rectitude of will for its own sake," the arguments of *On Truth* imply that freedom is also the capacity for justice and the capacity for moral praiseworthiness. Now it is both necessary and sufficient for justice, and thus for praiseworthiness, that an agent wills what is right, knowing it to be right, because it is right. That an agent wills what is right because it is right entails that he is neither compelled nor bribed to perform the act. Freedom, then, must be neither more nor less than the power to perform acts of that sort.

Freedom and sin

Thus Anselm takes it to be obvious that freedom is a power *for* something: its purpose is to preserve rectitude of will for its own sake. God and the good angels cannot sin, but they are still free, because they can (and do) preserve rectitude of will for its own sake. In fact, they are freer than those who can sin:

"someone who has what is fitting and expedient in such a way that he cannot lose it is freer than someone who has it in such a way that he can lose it and be seduced into what is unfitting and inexpedient" (*DLA* 1). It obviously follows, as Anselm points out, that freedom of choice neither is nor entails the power to sin; God and the good angels have freedom of choice, but they are incapable of sinning.

But if free choice is the power to hold on to what is fitting and expedient, and it is not the power to sin, does it make any sense to say that the first human beings and the rebel angels sinned through free choice? Anselm's reply to this question is both subtle and plausible. In order to be able to preserve rectitude of will for its own sake, an agent must be able to perform an action that has its ultimate origin in the agent him- or herself rather than in some external source. (For convenience I will refer to that power as "the power for self-initiated action.") Any being that has freedom of choice, therefore, will thereby have the power for self-initiated action. The first human beings and the rebel angels sinned through an exercise of their power for self-initiated action, and so it is appropriate to say that they sinned through free choice. Nonetheless, free choice does not entail the power to sin. For free choice can be perfected by something else, as yet unspecified, that renders it incapable of sinning.

In *On the Fall of the Devil* (*De casu diaboli*) Anselm extends his account of freedom and sin by discussing the first sin of the angels. In order for the angels to have the power to preserve rectitude of will for its own sake, they had to have both a will for justice and a will for happiness. If God had given them only a will for happiness, they would have been necessitated to will whatever they thought would make them happy. Their willing of happiness would have had its ultimate origin in God and not in the angels themselves. So they would not have had the power for self-initiated action, which means that they would not have had free choice. The same thing would have been true, *mutatis mutandis*, if God had given them only the will for justice.

Since God gave them both wills, however, they had the power for self-initiated action. Whether they chose to subject their wills for happiness to the demands of justice or to ignore the demands of justice in the interest of happiness, that choice had its ultimate origin in the angels; it was not received from God. The rebel angels chose to abandon justice in an attempt to gain happiness for themselves, whereas the good angels chose to persevere in justice even if it meant less happiness. God punished the rebel angels by taking away their happiness; he rewarded the good angels by granting them all the happiness they could possibly want. For this reason, the good angels are no longer able to sin. Since there is no further happiness left for them to will, their will for happiness can no longer entice them to overstep the bounds of justice. Thus Anselm finally explains what it is that perfects free choice so that it becomes unable to sin.

Grace and redemption

Like the fallen angels, the first human beings willed happiness in preference to justice. By doing so they abandoned the will for justice and became unable to will justice for its own sake. Apart from divine grace, then, fallen human beings cannot help but sin. Anselm claims that we are still free, because we continue to be such that if we had rectitude of will, we could preserve it for its own sake; but we cannot

exercise our freedom, since we no longer have the rectitude of will to preserve. (Whether fallen human beings also retain the power for self-initiated action apart from divine grace is a tricky question, and one I do not propose to answer here.)

So the restoration of human beings to the justice they were intended to enjoy requires divine grace. But even more is needed than God's restoration of the will for justice. In *Cur Deus Homo* (*Why the God-Man?* or *Why God Became Man*) Anselm famously attempts to show on purely rational grounds that the debt incurred by human sin could be suitably discharged, and the affront to God's infinite dignity could be suitably rectified, only if one who was both fully divine and fully human took it upon himself to offer his own life on our behalf.

Ontological Arguments

Ontological arguments are arguments, for the conclusion that God exists, from premises which are supposed to derive from some source other than observation of the world -- e.g., from reason alone. In other words, ontological arguments are arguments from nothing but analytic, *a priori* and necessary premises to the conclusion that God exists.

The first, and best-known, ontological argument was proposed by St. Anselm of Canterbury in the 11th. century A.D. In his *Proslogion*, St. Anselm claims to derive the existence of God from the concept of a *being than which no greater can be conceived*. St. Anselm reasoned that, if such a being fails to exist, then a greater being -- namely, a *being than which no greater can be conceived, and which exists* -- can be conceived. But this would be absurd: nothing can be greater than a being than which no greater can be conceived. So a being than which no greater can be conceived -- i.e., God -- exists.

In the seventeenth century, Rene Descartes defended a family of similar arguments. For instance, in the *Fifth Meditation*, Descartes claims to provide a proof demonstrating the existence of God from the idea of a supremely perfect being. Descartes argues that there is no less contradiction in conceiving a supremely perfect being who lacks existence than there is in conceiving a triangle whose interior angles do not sum to 180 degrees. Hence, he supposes, since we do conceive a supremely perfect being -- we do have the idea of a supremely perfect being -- we must conclude that a supremely perfect being exists.

In the early eighteenth century, Gottfried Leibniz attempted to fill what he took to be a shortcoming in Descartes' view. According to Leibniz, Descartes' arguments fail unless one first shows that the idea of a supremely perfect being is coherent, or that it is possible for there to be a supremely perfect being. Leibniz argued that, since perfections are unanalysable, it is impossible to demonstrate that perfections are incompatible -- and he concluded from this that all perfections can co-exist together in a single entity.

In more recent times, Kurt Gödel, Charles Hartshorne, Norman Malcolm and Alvin Plantinga have all presented much-discussed ontological arguments which bear interesting connections to the earlier arguments of St. Anselm, Descartes and Leibniz. Of these, the most interesting are those of Gödel and Plantinga; in these cases, however, it is unclear whether we should really say that these authors claim that the arguments are *proofs* of the existence of God.

Critiques of ontological arguments begin with Gaunilo, a contemporary of St. Anselm. Perhaps the best known criticisms of ontological arguments are due to Immanuel Kant, in his *Critique of Pure Reason*. Most famously, Kant claims that ontological arguments are vitiated by their reliance upon the implicit

assumption that "existence" is a predicate. However, as Bertrand Russell observed, it is much easier to be persuaded that ontological arguments are no good than it is to say exactly what is wrong with them. This helps to explain why ontological arguments have fascinated philosophers for almost a thousand years.

In various ways, the account provided to this point is rough, and susceptible of improvement. Sections 1 - 5 in what follows provide some of the requisite embellishments, though -- as is usually the case in philosophy -- there are many issues taken up here which could be pursued at much greater length. Sections 6 - 8 take up some of the central questions at a slightly more sophisticated level of discussion:

---

1. History of Ontological Arguments

1078: St. Anselm, *Proslogion*. Followed soon after by Gaunilo's critique *In Behalf of the Fool*.

1264: St. Thomas Aquinas, *Summa*. Criticises an argument which somehow descends from St. Anselm.

1637: Descartes, *Meditations*. The Objections -- particularly those of Caterus and Gassendi -- and the Replies contain much valuable discussion of the Cartesian arguments.

c1680: Spinoza, *Ethics*. Intimations of a defensible mereological ontological argument, albeit one whose conclusion is not (obviously) endowed with religious significance.

1709: Leibniz, *New Essays Concerning Human Understanding*. Contains Leibniz's attempt to complete the Cartesian argument by showing that the Cartesian conception of God is not inconsistent.

1776: Hume, *Dialogues Concerning Natural Religion*. Part IX is a general attack on *a priori* arguments (both analytic and synthetic). Includes a purported demonstration that no such arguments can be any good.

1787: Kant, *Critique of Pure Reason*. Contains famous attack on traditional theistic arguments. Three objections to "the ontological argument", including the famous objection based on the dictum that existence is not a predicate.

1831: Hegel, *Lectures of 1831*. Famous assertion -- uncontaminated by argument -- of the correctness of ontological arguments.

1884: Frege, *Foundations of Arithmetic*. Existence is a second-order predicate. First-order existence claims are meaningless. So ontological arguments -- whose conclusions are first-order existence claims -- are doomed.

1941: Hartshorne, *Man's Vision of God*. Defence of modal ontological arguments, allegedly derived from Proslogion 3.

1960: Malcolm, "Anselm's Ontological Argument". Defence of modal ontological arguments by a famous ordinary philosopher.

1970: Lewis, "Anselm and Actuality". The key critique of ontological arguments. All ontological arguments are either invalid or question-begging; moreover, in many cases, they have two closely related readings, one of which falls into each of the above categories.

1974: Plantinga, *The Nature of Necessity*. Plantinga's "victorious" modal ontological argument.

1995: Gödel, *Collected Works Volume III*. Gödel's ontological argument.

2. Taxonomy of Ontological Arguments

According to the taxonomy of Oppy (1995), there are seven major kinds of ontological arguments, viz:

1. definitional ontological arguments;
2. conceptual (or hyperintensional) ontological arguments;
3. modal ontological arguments;
4. Meinongian ontological arguments;
5. experiential ontological arguments;
6. mereological ontological arguments; and
7. ‘Hegelian’ ontological arguments.

Examples of each follow. These are mostly toy examples. But they serve to highlight the deficiencies which more complex examples also share.

> 1. God is a being which has every perfection. (This is true as a matter of definition.) Existence is a perfection. Hence God exists.

> 2. I conceive of a being than which no greater can be conceived. If a being than which no greater can be conceived does not exist, then I can conceive of a being greater than a being than which no greater can be conceived -- namely, a being than which no greater can be conceived that exists. I cannot conceive of a being greater than a being than which no greater can be conceived. Hence, a being than which no greater can be conceived exists.

> 3. It is possible that that God exists. God is not a contingent being, i.e., either it is not

possible that God exists, or it is necessary that God exists. Hence, it is necessary that God exists. Hence, God exists. (See Malcolm (1960), Hartshorne (1965), and Plantinga (1974) for closely related arguments.)

4. [It is analytic, necessary and a priori that] Each instance of the schema "The F G is F" expresses a truth. Hence the sentence "The existent perfect being is existent" expresses a truth. Hence, the existent perfect being is existent. Hence, God is existent, i.e. God exists. (The last step is justified by the observation that, as a matter of definition, if there is exactly one existent perfect being, then that being is God.)

5. The word ‘God’ has a meaning that is revealed in religious experience. The word ‘God’ has a meaning only if God exists. Hence, God exists. (See Rescher (1959) for a live version of this argument.)

6. I exist. Therefore something exists. Whenever a bunch of things exist, their mereological sum also exists. Therefore the sum of all things exists. Therefore God -- the sum of all things -- exists.

7. God must exist.

Of course, this taxonomy is not exclusive: an argument can belong to several categories at once. Moreover, an argument can be ambiguous between a range of readings, each of which belongs to different categories. This latter fact may help to explain part of the curious fascination of ontological arguments. Finally, the taxonomy can be further specialised: there are, for example, at least four importantly different kinds of modal ontological arguments which should be distinguished. (See, e.g., Ross (1969) for a rather different kind of modal ontological argument.)

3. Characterisation of Ontological Arguments

It is not easy to give a good characterisation of ontological arguments. The traditional characterisation involves the use of problematic notions -- analyticity, necessity, and *a priority* -- and also fails to apply to many arguments to which defenders have affixed the label "ontological". (Consider, for example, the claim that I conceive of a being than which no greater can be conceived. This claim is clearly not analytic (its truth doesn't follow immediately from the meanings of the words used to express it), nor necessary (I might never have entertained the concept), nor *a priori* (except perhaps in my own case, though even this is unclear -- perhaps even I don't know independently of experience that I have this concept.)) However, it is unclear how that traditional characterisation should be improved upon.

Perhaps one might resolve to use the label "ontological argument" for any argument which gets classified as "an ontological argument" by its proponent(s). This procedure would make good sense if one thought that there is a natural kind -- ontological arguments -- which our practice carves out, but for which is hard to specify defining conditions. Moreover, this procedure can be adapted as a *pro tem* stop gap: when there

is a better definition to hand, that definition will be adopted instead. On the other hand, it seems worthwhile to attempt a more informative definition.

Focus on the case of ontological arguments for the conclusion that God exists. One characteristic feature of these arguments is the use which they make of "referential vocabulary" -- names, definite descriptions, indefinite descriptions, quantified noun phrases, etc. -- whose ontological commitments -- for occurrences of this vocabulary in "referential position" -- non-theists do not accept.

Theists and non-theists alike (can) agree that there is spatio-temporal, or causal, or nomic, or modal structure to the world (the basis for cosmological arguments); and that there are certain kinds of complexity of organisation, structure and function in the world (the basis for teleological arguments); and so on. But theists and non-theists are in dispute about whether there are perfect beings, or beings than which no greater can be conceived, or ... ; thus, theists and non-theists are in dispute about the *indirect* subject matter of the premises of ontological arguments.

Of course, the premises of ontological arguments often do not deal directly with perfect beings, beings than which no greater can be conceived, etc.; rather, they deal with descriptions of, or ideas of, or concepts of, or the possibility of the existence of, these things. However, the basic point remains: ontological arguments require the use of vocabulary which non-theists should certainly find problematic when it is used in ontologically committing contexts (i.e not inside the scope of prophylactic operators -- such as "according to the story" or "by the lights of theists" or "by the definition" -- which can be taken to afford protection against unwanted commitments).

Note that this characterisation does not beg the question against the possibility of the construction of a successful ontological argument -- i.e., it does not lead immediately to the conclusion that all ontological arguments are question-begging (in virtue of the ontologically committing vocabulary which they employ). For it may be that the vocabulary in question only gets used in premises under the protection of prophylactic operators (which ward off the unwanted commitments.) Of course, there will then be questions about whether the resulting arguments can possibly be valid -- how could the commitments turn up in the conclusion if they are not there in the premises? -- but those are further questions, which would remain to be addressed.

4. Objections to Ontological Arguments

Objections to ontological arguments take many forms. Some objections are intended to apply only to particular ontological arguments, or particular forms of ontological arguments; other objections are intended to apply to all ontological arguments. It is a controversial question whether there are any successful general objections to ontological arguments.

One general criticism of ontological arguments which have appeared hitherto is this: none of them is *persuasive*, i.e., none of them provides those who do not already accept the conclusion that God exists -- and who are reasonable, reflective, well-informed, etc. -- with either a *pro tanto* reason or an all-things-

considered reason to accept that conclusion. Any reading of any ontological argument which has been produced so far which is sufficiently clearly stated to admit of evaluation yields a result which is invalid, or possesses a set of premises which it is clear in advance that no reasonable, reflective, well-informed, etc. non-theists will accept, or has a benign conclusion which has no religious significance, or else falls prey to more than one of the above failings.

For each of the families of arguments introduced in the earlier taxonomy, we can give general reasons why arguments of that family fall under the general criticism. In what follows, we shall apply these general considerations to the exemplar arguments introduced in section 2.

(1) Definitional arguments: These are arguments in which ontologically committing vocabulary is introduced solely via a definition. An obvious problem is that claims involving that vocabulary cannot then be non-question-beggingly detached from the scope of that definition. (The inference from ‘By definition, God is an existent being’ to ‘God exists’ is patently invalid; while the inference to ‘By definition, God exists’ is valid, but uninteresting. In the example given earlier, the premises licence the claim that, as a matter of definition, God possesses the perfection of existence. But, as just noted, there is no valid inference from this claim to the further claim that God exists.)

(2) Conceptual arguments: These are arguments in which ontologically committing vocabulary is introduced solely within the scope of hyperintensional operators (e.g. ‘believes that’, ‘conceives of’, etc.). Often, these operators have two readings, one of which can cancel ontological commitment, and the other of which cannot. On the reading which can give cancellation (as in the most likely reading of ‘John believes in Santa Claus’), the inference to a conclusion in which the ontological commitment is not cancelled will be invalid. On the reading which cannot cancel ontological commitment (as in that reading of ‘John thinks about God’ which can only be true if there is a God to think about), the premises are question-begging: they incur ontological commitments which non-theists reject. In our sample argument, the claim, that I conceive of an existent being than which no greater being can be conceived, admits of the two kinds of readings just distinguished. On the one hand, on the reading which gives cancellation, the inference to the conclusion that there is a being than which no greater can be conceived is plainly invalid. On the other hand, on the reading in which there is no cancellation, it is clear that this claim is one which no reasonable, etc. non-theist will accept: if you doubt that there is a being than which no greater can be conceived, then, of course, you doubt whether you can have thoughts *about* such a being.

(3) Modal arguments: These are arguments with premises which concern modal claims about God, i.e., claims about the possibility or necessity of God's attributes and existence. Suppose that we agree to think about possibility and necessity in terms of possible worlds: a claim is possibly true just in case it is true in at least one possible world; a claim is necessarily true just in case it is true in every possible world; and a claim is contingent just in case it is true in some possible worlds and false in others. Some theists hold that God is a necessarily existent being, i.e., that God exists in every possible world. Non-theists do not accept the claim that God exists in the actual world. Plainly enough, non-theists and necessitarian theists disagree about the layout of logical space, i.e., the space of possible worlds. The sample argument consists, in effect, of two premises: one which says that God exists in at least one possible world; and one which says that God exists in all possible worlds if God exists in any. It is perfectly obvious that no non-

theist can accept this pair of premises. Of course, a non-theist can allow -- if they wish -- that there are possible worlds in which there are contingent Gods. However, it is quite clear that no rational, reflective, etc. non-theist will accept the pair of premises in the sample argument.

(4) Meinongian arguments: These are arguments which depend somehow or other on Meinongian theories of objects. Consider the schema ‘The F G is F’. Naive Meinongians will suppose that if F is instantiated with any property, then the result is true (and, quite likely, necessary, analytic and a priori). So, for example, the round square is round; the bald current King of France is bald; and so on. However, more sophisticiated Meinongians will insist that there must be some restriction on the substitution instances for F, in order to allow one to draw the obvious and important ontological distinction between the following two groups: {Bill Clinton, the sun, the Eiffel Tower} and {Santa Claus, Mickey Mouse, the round square}. Choice of vocabulary here is controversial: Let us suppose (for the sake of example) that the right thing to say is that the former things exist and the latter do not. Under this supposition, ‘existent’ will not be a suitable substitution instance for F -- obviously, since we all agree that there is no existent round square. Of course, nothing hangs on the choice of ‘existent’ as the crucial vocabulary. The point is that non-theists are not prepared to include god(s) in the former group of objects -- and hence will be unpersuaded by any argument which tries to use whatever vocabulary is used to discriminate between the two classes as the basis for an argument that god(s) belong to the former group. (Cognoscenti will recognise that the crucial point is that Meinongian ontological arguments fail to respect the distinction between nuclear (assumptible, characterising) properties and non-nuclear (non-assumptible, non-characterising) properties. It should, of course, be noted that neither Meinong, nor any of his well-known modern supporters -- e.g. Terence Parsons, Richard Sylvan -- ever endorses a Meinongian ontological argument; and it should also be noted that most motivate the distinction between nuclear and non-nuclear properties in part by a need to avoid Meinongian ontological arguments. The reason for calling these arguments "Meinongian" is that they rely on quantification over -- or reference to -- non-existent objects; there is no perjorative intent in the use of this label.)

(5) Experiential arguments: These are arguments which try to make use of ‘externalist’ or ‘object-involving’ accounts of content. It should not be surprising that they fail. After all, those accounts of content need to have something to say about expressions which fail to refer (‘Santa Claus’, ‘phlogiston’, etc.). But, however the account goes, non-theists will insist that expressions which purport to refer to god(s) should be given exactly the same kind of treatment.

(6) Mereological arguments: Those who dislike mereology will not be impressed by these arguments. However, even those who accept principles of unrestricted composition -- i.e., who accept principles which claim, e.g., that, whenever there are some things, there is something which is the sum or fusion of all of those things -- need not be perturbed by them: for it is plausible to think that the conclusions of these arguments have no religious significance whatsoever -- they are merely arguments for, e.g., the existence of the physical universe.

(7) ‘Hegelian arguments’: Since these are not strictly speaking arguments -- but merely unsupported assertions -- there is nothing to refute.

Even if the forgoing analyses are correct, it is important to note that no argument has been given for the conclusion that no ontological argument *can* be successful. Even if all of the kinds of arguments produced to date are pretty clearly unsuccessful -- i.e., not such as ought to give non-theists reason to accept the conclusion that God exists -- it remains an open question whether there is some other kind of hitherto undiscovered ontological argument which does succeed. (Perhaps it is worth adding here that there is fairly widespread consensus, even amongst theists, that no known ontological arguments for the existence of God are persuasive. Most categories of ontological argument have some actual defenders; but none has a large following.)

Many other objections to (some) ontological arguments have been proposed. All of the following have been alleged to be the key to the explanation of the failure of (at least some) ontological arguments: (1) existence is not a predicate (see, e.g., Kant, Smart (1955), Alston (1960)); (2) the concept of god is meaningless/incoherent/ inconsistent (see, e.g., Findlay (1949)); (3) ontological arguments are ruled out by "the missing explanation argument" (see Johnston (1992); (4) ontological arguments all trade on mistaken uses of singular terms (see, e.g., Barnes (1972); (5) existence is not a perfection (see almost any textbook in philosophy of religion); (6) ontological arguments presuppose a Meinongian approach to ontology (see, e.g., Dummett (1993)); and (7) ontological arguments are question-begging, i.e., presuppose what they set out to prove (see, e.g., Rowe (1989)). There are many things to say about these objections: the most important point is that almost all of them require far more controversial assumptions than non-theists require in order to be able to reject ontological arguments with good conscience. Trying to support most of these claims merely in order to beat up on ontological arguments is like using a steamroller to crack a nut (in circumstances in which one is unsure that one can get the steamroller to move!).

Of course, all of the above discussion is directed merely to the claim that ontological arguments are not dialectically efficacious -- i.e., they give reasonable non-theists no reason to change their views. It might be wondered whether there is some other use which ontological arguments have -- e.g., as Plantinga claims, in establishing the reasonableness of theism. This seems unlikely. After all, at best these arguments show that certain sets of sentences (beliefs, etc.) are incompatible -- one cannot reject the conclusions of these arguments while accepting their premises. But the arguments themselves say nothing about the reasonableness of accepting the premisses. So the arguments themselves say nothing about the (unconditional) reasonableness of accepting the conclusions of these arguments. Those who are disposed to think that theism is irrational need find nothing in ontological arguments to make them change their minds (and those who are disposed to think that theism is true should take no comfort from them either).

5. Parodies of Ontological Arguments

Positive ontological arguments -- i.e., arguments FOR the existence of god(s) -- invariably admit of various kinds of parodies, i.e., parallel arguments which seem at least equally acceptable to non-theists, but which establish absurd or contradictory conclusions. For many positive ontological arguments, there are parodies which purport to establish the non-existence of god(s); and for many positive ontological arguments there are lots (usually a large infinity!) of similar arguments which purport to establish the

existence of lots (usally a large infinity) of distinct god-like beings. Here are some modest examples:

(1) By definition, God is a non-existent being who has every (other) perfection. Hence God does not exist.

(2) I conceive of a being than which no greater can be conceived except that it only ever creates N universes. If such a being does not exist, then we can conceive of a greater being -- namely, one exactly like it which does exist. But I cannot conceive of a being which is greater in this way. Hence, a being than which no greater can be conceived except that it only ever creates N universes exists.

(3) It is possible that God does not exist. God is not a contingent being, i.e., either it is not possible that God exists, or it is necessary that God exists. Hence it is not possible that God exists. Hence God does not exist.

(4) It is analytic, necessary, and a priori that the F G is F. Hence, the existent perfect being who creates exactly N universes is existent. Hence the perfect being who creates exactly N universes exists.

There are many kinds of parodies on Ontological Arguments. The aim is to construct arguments which non-theists can reasonably claim to have no more reason to accept than the original Ontological Arguments themselves. Of course, theists may well be able to hold that the originals are sound, and the parodies not -- but that is an entirely unrelated issue. (All theists -- and no non-theists -- should grant that the following argument is sound, given that the connectives are to be interpretted classically: "Either 2+2=5, or God exists. Not 2+2=5. Hence God exists." It should be completely obvious that this argument is useless.)

There are some very nice parodic discussions of Ontological Arguments in the literature. A particularly pretty one is due to Raymond Smullyan, in *5000 BC and Other Philosophical Fantasies*, in which the argument is attributed to "the unknown Dutch theologian van Dollard". A relatively recent addition to the genre is described in Grey (2000), though the date of its construction is uncertain. It is the work of Douglas Gasking, one time Professor of Philosophy at the University of Melbourne (with emendations by William Grey and Denis Robinson):

1. The creation of the world is the most marvellous achievement imaginable.
2. The merit of an achievement is the product of (a) its intrinsic quality, and (b) the ability of its creator.
3. The greater the disability or handicap of the creator, the more impressive the achievement.
4. The most formidable handicap for a creator would be non-existence.
5. Therefore, if we suppose that the universe is the product of an existent creator, we can conceive a greater being -- namely, one who created everything while not existing.
6. An existing God, therefore, would not be a being than which a greater cannot be conceived, because an even more formidable and incredible creator would be a God which did not exist.
7. (Hence) God does not exist.

This parody -- at least in its current state -- seems to me to be inferior to other parodies in the literature, including the early parodies of Gaunilo and Caterus. To mention but one difficulty, while we *might* suppose that it would be a greater achievement to create something if one did not exist than if one did exist, it doesn't follow from this that a non-existent creator is greater (*qua* being) than an existent creator. Perhaps it might be replied that this objection fails to take the first premise into account: if the creation of the world really is "the most marvellous achievement imaginable", then surely there is some plausibility to the claim that the creator must have been non-existent (since that would make the achievement more marvellous than it would otherwise have been). But what reason is there to believe that the creation of the world is "the most marvellous achievement imaginable", in the sense which is required for this argument? Surely it is quite easy to imagine even more marvellous achievements -- e.g., the creation of many worlds at least as good as this one! (Of course, one might also want to say that, in fact, one cannot conceive of a non-existent being's actually creating something: that is literally inconceivable. Etc.)

6. Gödel's Ontological Argument

There is a small, but steadily growing, literature on the ontological arguments which Gödel developed in his notebooks, but which did not appear in print until well after his death. These arguments have been discussed, annotated and amended by various leading logicians: the upshot is a family of arguments with impeccable *logical* credentials. (Interested readers are referred to Sobel (1987), Anderson (1990), Adams (1995b), and Hazen (1999) for the history of these arguments, and for the scholarly annotations and emendations.) Here, I shall give a brief presentation of the version of the argument which is developed by Anderson, and then make some comments on *that* version. This discussion follows the presentation and discussion in Oppy (1996)(2000).

> Definition 1: *x* is God-like iff *x* has as essential properties those and only those properties which are positive
>
> Definition 2: *A* is an essence of *x* iff for every property *B*, *x* has *B* necessarily iff *A* entails *B*
>
> Definition 3: *x* necessarily exists iff every essence of *x* is necessarily exemplified
>
> Axiom 1: If a property is positive, then its negation is not positive.
>
> Axiom 2: Any property entailed by -- i.e., strictly implied by -- a positive property is positive
>
> Axiom 3: The property of being God-like is positive
>
> Axiom 4: If a property is positive, then it is necessarily positive
>
> Axiom 5: Necessary existence is positive

> Axiom 6: For any property *P*, if *P* is positive, then being necessarily P is positive.
>
> Theorem 1: If a property is positive, then it is consistent, i.e., possibly exemplified.
>
> Corollary 1: The property of being God-like is consistent.
>
> Theorem 2: If something is God-like, then the property of being God-like is an essence of that thing.
>
> Theorem 3: Necessarily, the property of being God-like is exemplified.

Given a sufficiently generous conception of properties, and granted the acceptability of the underlying modal logic, the listed theorems do follow from the axioms. (This point was argued in detail by Dana Scott, in unpublished lecture notes which circulated for many years. It is also made by Sobel, Anderson, and Adams.) So, criticisms of the argument are bound to focus on the axioms, or on the other assumptions which are required in order to construct the proof.

Some philosophers have denied the acceptability of the underlying modal logic. And some philosophers have rejected generous conceptions of properties in favour of sparse conceptions according to which only some predicates express properties. But suppose that we adopt neither of these avenues of potential criticism of the proof. What else might we say against it?

One important point to note is that no *definition* of the notion of "positive property" is supplied with the proof. At most, the various axioms which involve this concept can be taken to provide a *partial* implicit definition. If we suppose that the "positive properties" form a set, then the axioms provide us with the following information about this set:

1. If a property belongs to the set, then its negation does not belong to the set.
2. The set is closed under entailment.
3. The property of having as essential properties just those properties which are in the set is itself a member of the set.
4. The set has exactly the same members in all possible worlds.
5. The property of necessary existence is in the set.
6. If a property is in the set, then the property of having that property necessarily is also in the set.

On Gödel's theoretical assumptions, we can show that *any* set which conforms to (1) - (6) is such that the property of having as essential properties just those properties which are in *that* set is exemplified. Gödel wants us to conclude that there is just one intuitive, theologically interesting set of properties which is such that the property of having as essential properties just the properties in that set is exemplified. But, on the one hand, what reason do we have to think that there is *any* theologically interesting set of properties which conforms to the Gödelian specification? And, on the other hand, what reason do we have

to deny that, if there is one set of theologically interesting set of properties which conforms to the Gödelian specification, then there are many theologically threatening sets of properties which also conform to that specification?

In particular, there is some reason to think that the Gödelian ontological argument goes through just as well -- or just as badly -- with respect to other sets of properties (and in ways which are damaging to the original argument). Suppose that there is some set of independent properties {*I*, *G*1, *G*2, ...} which can be used to generate the set of positive properties by closure under entailment and "necessitation". ("Independence" means: no one of the properties in the set is entailed by all the rest. "Necessitation" means: if *P* is in the set, then so is necessarily having *P*. *I* is the property of having as essential properties just those properties which are in the set. *G*1, *G*2, ... are further properties, of which we require at least two.) Consider any proper subset of the set {*G*1, *G*2, ...} -- {*H*1, *H*2, ...}, say -- and define a new generating set {*I**, *H*1, *H*2, ...}, which *I** is the property of having as essential properties just those properties which are in the newly generated set. A "proof" parallel to that offered by Gödel "establishes" that there is a being which has as essential properties just those properties in this new set. If there are as few as 7 independent properties in the original generating set, then we shall be able to establish the existence of 720 distinct"God-like" creatures by the kind of argument which Gödel offers. (The creatures are distinct because each has a different set of essential properties.)

Even if the above considerations are sufficient to cast doubt on the credentials of Gödel's "proof", they do not pinpoint where the "proof" goes wrong. If we accept that the role of Axioms 1, 2, 4, and 6 is really just to constrain the notion of "positive property" in the right way -- or, in other words, if we suppose that Axioms 1, 2, 4, and 6 are "analytic truths" about "positive properties" -- then there is good reason for opponents of the "proof" to be sceptical about Axioms 3 and 5. Kant would not have been happy with Axiom 5; and there is at least some reason to think that whether the property of being God-like is "positive" ought to depend upon whether or not there is a God-like being.

7. Plantinga's Ontological Argument

The "victorious" modal ontological argument of Plantinga (1974) goes roughly as follows: Say that an entity possesses "maximal excellence" iff it is omnipotent, omnscient, and morally perfect. Say, further, that an entity possesses "maximal greatness" iff it possesses maximal excellence in every possible world -- that is, iff it is necessarily existent and necessarily maximally excellent. Then consider the following argument:

1. There is a possible world in which there is an entity which possesses maximal greatness.
2. (Hence) There is an entity which possesses maximal greatness.

Under suitable assumptions about the nature of accessibility relations between possible worlds, this argument is valid: from it is possible that it is necessary that *p*, one can infer that it is necessary that *p*. Setting aside the possibility that one might challenge this widely accepted modal principle, it seems that opponents of the argument are bound to challenge the acceptability of the premise.

And, of course, they do. Let's just run the argument in reverse.

1. There is no entity which possesses maximal greatness.
2. (Hence) There is no possible world in which there is an entity which possesses maximal greatness.

Plainly enough, if you do not already accept the claim that there is an entity which possesses maximal greatness, then you won't agree that the first of these arguments is more acceptable than the second. So, as a proof of the existence of a being which posseses maximal greatness, Plantinga's argument seems to be a non-starter.

Perhaps somewhat surprisingly, Plantinga himself agrees: the "victorious" modal ontological argument is not a proof of the existence of a being which possesses maximal greatness. But how, then, is it "victorious"? Plantinga writes: "Our verdict on these reformulated versions of St. Anselm's argument must be as follows. They cannot, perhaps, be said to *prove* or *establish* their conclusion. But since it is rational to accept their central premise, they do show that it is rational to accept that conclusion." (Plantinga (1974:221)).

It is pretty clear that Plantinga's argument does not show what he claims that it shows. Consider, again, the argument: "Either God exists, or 2+2=5. It is not the case that 2+2=5. So God exists." It is just a mistake for a theist to say: "Since the premise is *true* (and the argument is valid), this argument *shows* that the conclusion of the argument is *true*". No-one thinks that that argument *shows* any such thing. Similarly, it is just a mistake for a theist to say: "Since it is *rational* to accept the premise (and the argument is valid), this argument *shows* that it is *rational* to accept the conclusion of the argument". Again, no one thinks that that argument *shows* any such thing. But why don't these arguments *show* the things in question? There is room for argument about this. But it is at least plausible to claim that, in each case, any even minimally rational person who has doubts about the claimed status of the conclusion of the argument will have exactly the same doubts about the claimed status of the premise. If, for example, I doubt that it is rational to accept the claim that God exists, then you can quite sure that I will doubt that it is rational to accept the claim that either 2+2=5 or God exists. But, of course, the very same point can be made about Plantinga's argument: anyone with even minimal rationality who understands the premise and the conclusion of the argument, and who has doubts about the claim that there is an entity which possesses maximal greatness, will have exactly the same doubts about the claim that there is a possible world in which there is an entity which possesses maximal greatness.

For further discussion of Plantinga's argument, see -- for example -- Adams (1988), Chandler (1993), Oppy (1995:70-78, 248-259), Tooley (1981), and van Inwagen (1977)).

8. St. Anselm's Ontological Argument

There is an enormous literature on the material in *Proslogion II-III*. Some commentators deny that St. Anselm tried to put forward any proofs of the existence of God. Even among commentators who agree

that St. Anselm intended to prove the existence of God, there is disagreement about where the proof is located. Some commentators claim that the main proof is in *Proslogion II*, and that the rest of the work draws out corollaries of that proof (see, e.g., Charlesworth (1965)). Other commentators claim that the main proof is in *Prologion III*, and that the proof in *Proslogion II* is merely an inferior first attempt (see, e.g., Malcolm (1960)). Yet other commentators claim that there is a single proof which spans at least *Proslogion II-III* -- see, e.g., Campbell (1976) and, perhaps, the entire work -- see, e.g., La Croix (1972). I shall ignore this aspect of the controversy about the *Proslogion*. Instead, I shall just focus on the question of the analysis of the material in *Proslogion II* on the assumption that there is an independent argument for the existence of God which is given therein.

Here is one translation of the crucial part of *Proslogion II* (due to William Mann (1972:260-1); alternative translations can be found in Barnes (1972), Campbell (1976), Charlesworth (1965), and elsewhere):

> Thus even the fool is convinced that something than which nothing greater can be conceived is in the understanding, since when he hears this, he understands it; and whatever is understood is in the understanding. And certainly that than which a greater cannot be conceived cannot be in the understanding alone. For if it is even in the understanding alone, it can be conceived to exist in reality also, which is greater. Thus if that than which a greater cannot be conceived is in the understanding alone, then that than which a greater cannot be conceived is itself that than which a greater can be conceived. But surely this cannot be. Thus without doubt something than which a greater cannot be conceived exists, both in the understanding and in reality.

There have been many ingenious attempts to find an argument which can be expressed in modern logical formalism, which is logically valid, and which might plausibly be claimed to be *the* argument which is expressed in this passage. To take a few prime examples, Adams (1971), Barnes (1972) and Oppenheimer and Zalta (1991) have all produced formally valid analyses of the argument in this passage. We begin with a brief presentation of each of these analyses, preceded by a presentation of the formulation of the argument given by Plantinga (1967), and including a presentation of some of the formulations of Lewis (1970). (Chambers (2000) works with the analysis of Adams (1971).)

Plantinga

1. God exists in the understanding but not in reality.	(Assumption for *reductio*)
2. Existence in reality is greater than existence in the understanding alone.	(Premise)
3. A being having all of God's properties plus existence in reality can be conceived.	(Premise)
4. A being having all of God's properties plus existence in reality is greater than God	(From (1) and (2).)
5. A being greater than God can be conceived.	(From (3) and (4).)

6. It is false that a being greater than God can be conceived. (From definition of "God".)
7. Hence, it is false that God exists in the understanding but not in reality. (From (1), (5), (6).)
8. God exists in the understanding. (Premise, to which even the Fool agrees.)
9. Hence God exists in reality. (From (7), (8).)

Barnes

1. The Fool understands the expression "the being than which no greater can be conceived". (Premise)
2. If a person understands an expression "*b*", then *b* is in that person's understanding. (Premise)
3. If a thing is in a person's understanding, then the person can conceive of that thing's existing in reality. (Premise)
4. Each thing which exists in reality is greater than any thing which exists only in the understanding. (Premise)
5. If a person can conceive of something, and that thing entails something else, then the person can also conceive of that other thing. (Premise)
6. If a person can conceive that a specified object has a given property, then that person can conceive that something or other has that property. (Premise)
7. Hence the being than which no greater can be conceived exists in reality. (From (1)-(6), by a complex series of steps here omitted.)

Adams

1. There is a thing *x*, and a magnitude *m*, such that *x* exists in the understanding, *m* is the magnitude of *x*, and it it not possible that there is a thing *y* and a magnitude *n* such that *n* is the magnitude of *y* and $n>m$. (Premise)
2. For any thing *x* and magnitude *m*, if *x* exists in the understanding, *m* is the magnitude of *x*, and it is not possible that there is a thing *y* and magnitude *n* such that *n* is the magnitude of *y* and $n>m$, then it is possible that *x* exists in reality. (Premise)
3. For any thing *x* and magnitude *m*, if *m* is the magnitude of *x*, and it it not possible that there is a thing *y* and a magnitude *n* such that *n* is the magnitude of *y* and $n>m$, and *x* does not exist in reality, then it is not possible that if *x* exists in reality then there is a magnitude *n* such that *n* is greater than *m* and *n* is the magnitude of *x*. (Premise)

4. (Hence) There is a thing *x* and a magnitude *m* such that *x* exist in the understanding, and *x* exists in reality, and *m* is the magnitude of *x*, and it it not possible that there is a thing *y* and a magnitude *n* such that *n* is the magnitude of *y* and *n*>*m*. (From 1, 2, 3)

Lewis

1. For any understandable being *x*, there is a world *w* such that *x* exists in *w*. (Premise)
2. For any understandable being *x*, and for any worlds *w* and *v*, if *x* exists in *w*, but *x* does not exist in *v*, then the greatness of *x* in *w* exceeds the greatness of *x* in *v*. (Premise)
3. There is an understandable being *x* such that for no world *w* and being *y* does the greatness of *y* in *w* exceed the greatness of *x* in the actual world. (Premise)
4. (Hence) There is a being *x* existing in the actual world such that for no world *w* and being *y* does the greatness of *y* in *w* exceed the greatness of *x* in the actual world. (From (1)-(3).)

Lewis also suggests an alternative to (3) which yields a valid argument:

> (3′) There is an understandable being *x* such that for no worlds *v* and *w* and being *y* does the greatness of *y* in w exceed the greatness of *x* in *v*.

and two alternatives to (3) -- not presented here -- which yield invalid arguments. (Of course, there further two alternatives are crucial to Lewis' overall analysis of the passage: essentially, Lewis suggests that Anselm equivocates between an invalid argument with plausible premises and a valid argument with question-begging premises. In this respect, Lewis' analysis is quite different from the other analyses currently under discussion.)

Oppenheimer and Zalta

1. There is (in the understanding) something than which there is no greater. (Premise)
2. (Hence) There is (in the understanding) a unique thing than which there is no greater. (From (1), assuming that the "greater-than" relation is connected.)
3. (Hence) There is (in the understanding) something which is the thing than which there is no greater. (From (2), by a theorem about descriptions.)
4. (Hence) There is (in the understanding) nothing which is greater than the thing than which there is no greater. (From (3), by another theorem about descriptions.)

5. If that thing than which there is no greater does not exist (in reality), then there is (in the understanding) something which is greater than that thing than which there is no greater. (Premise)
6. (Hence) That thing than which there is no greater exists (in reality). (From (4) and (5).)
7. (Hence) God exist. (From (6).)

Critical Appraisal

Considered as interpretations of the argument presented in the *Proslogion*, these formulations are subject to various kinds of criticisms.

First, the modal interpretations of Lewis (1970) and Adams (1971) don't square very well with the rest of the *Proslogion*: the claim that "being than which no greater can be conceived" should be read as "being than which no greater is possible" would have us render the claim of *Proslogion 15* to be that God is a being greater than any which is possible. And that is surely a bad result.

Second, the Meinongian interpretations of Barnes (1972), Adams (1971) and Oppenheimer and Zalta (1991) produce arguments which, given the principles involved, could easily be much simplified, and which are *obviously* vulnerable to Gaunilo-type objections.

Consider, for example, the case of Oppenheimer and Zalta. They have Anselm committed to the claim that if anyone can understand the phrase "that than which F", then there is something in the understanding such that F (see their footnote 25); and they also have him committed to the claim that if there is something which is the F-thing, then it -- i.e., the F-thing -- has the property F (see page 7). Plainly though, if Anselm is really committed to these principles, then he could hardly fail to be committed to the more general principles: (1) if anyone can understand the phrase "an F", then there is at least one F-thing in the understanding; and (2) if there are some things which are the F-things, then they -- i.e., the F-things -- must have the property F. (It would surely be absurd to claim that Anselm is only committed to the less general principles: what could possibly have justified the restrictions to the special cases?)

But, then, mark the consequences. We all understand the expression "an existent perfect being". So, by the first claim, there is at least one existent perfect being in the understanding. And, by the second claim, any existent perfect being is existent. So, from these two claims combined, there is -- in reality -- at least one existent perfect being.

This argument gives Anselm everything that he wants, and very much more briefly. (The *Proslogion* goes on and on, trying to establish the properties of that than which no greater can be conceived. How much easier if we can just explicitly build all of the properties which want to "derive" into the initial description.) So, if Anselm really were committed to the principles which Oppenheimer and Zalta appear

to attribute to him, it is hard to understand why he didn't give the simpler argument. And, of course, it is also hard to understand why he didn't take Gaunilo's criticism. After all, when it is set out in this way, it is obvious that the argument proves far too much.

Third, some of the arguments have Anselm committed to claims about greatness which do not seem to correspond with what he actually says. The natural reading of the text is that, if two beings are identical save that one exists only in the understanding and the other exists in reality as well, then the latter is greater than the former. But Barnes (1971), for example, has Anselm committed to the much stronger claim that any existing thing is greater than every non-existent thing.

Given these kinds of considerations, it is natural to wonder whether there are *better* interpretations of *Proslogion II* according to which the argument in question turns out *NOT* to be logically valid. Here is a modest attempt to provide such an analysis:

We start with the claim that the Fool understands the expression "being than which no greater can be conceived", i.e., even the Fool can entertain the idea or possess the concept of a being than which no greater can be conceived. Now, entertaining this idea or possessing this concept requires the entertainer or possessor to recognise certain relationships which hold between given properties and the idea or concept in question. For example, given that you possess the concept of, or entertain the idea of, a smallest really existent Martian, it follows that you must recognise some kind of connection between the properties of being a Martian, really existing, and being smaller than other really existing Martians, and the concept or idea in question.

Following Anselm, we might say that, since you understand the expression "smallest really existent Martian", there is, in your understanding, at least one smallest really existent Martian. (Or, apparently following Descartes, one might say that real existence is "part of" -- or "contained in" -- the idea of a smallest really existent Martian.) However, in saying this, it must be understood that we are not actually predicating properties of anything: we aren't supposing that there is something which possesses the properties of being a Martian, really existing, and being no larger than any other Martian. (After all, we can safely suppose, we don't think that any Martians really exist.) In other words, we must be able to have the concept of, or entertain the idea of, a smallest really existing Martian without believing that there really are any smallest Martians. Indeed, more strongly, we must be able to entertain the concept of a smallest really existent Martian -- and to recognise that the property of "really existing" is part of this concept -- while nonetheless maintaining that there are no smallest existent Martians.

It will be useful to introduce vocabulary to mark the point which is being made here. We could, for instance, distinguish between the properties which are *encoded* in an idea or concept, and the properties which are *attributed* in positive atomic beliefs which have that idea or concept as an ingredient. The idea "really existent Santa Claus" encodes the property of real existence; but it is perfectly possible to entertain this idea without attributing real existence to Santa Claus, i.e., without believing that Santa Claus really exists.

We can then apply this distinction to Anselm's argument. On the one hand, the idea "being than which no

greater can be conceived" encodes the property of real existence -- this is what the *reductio* argument establishes (if it establishes anything at all). On the other hand, it is perfectly possible to entertain the idea of a being than which no greater can be conceived -- and to recognise that this idea encodes the property of real existence -- without attributing real existence to a being than which no greater can be conceived, i.e., without believing that a being than which no greater can be conceived really exists.

Of course, the argument which Anselm actually presents pays no attention to this distinction between encoding and attributing -- i.e., between entertaining an idea and bolding a belief -- and nor does it pay attention to various other niceties. We begin from the point that the Fool entertains the idea of that than which no greater can be conceived (because the Fool understands the words "that than which no greater can be conceived"). From this, we move quickly to the claim that even the Fool is "convinced" -- i.e., believes -- that that than which no greater can be conceived possesses the property of existing in the understanding. And then the *reductio* argument is produced to establish that that than which no greater can be conceived cannot exist only in the understanding but must also possess the property of existing in reality as well (and all mention of the Fool, and what it is that the Fool believes, disappears).

As it stands, this is deeply problematic. How are we supposed to regiment the references to the Fool in the argument? Is the *reductio* argument supposed to tell us something about what even the Fool believes, or ought to believe? Are the earlier references to the Fool supposed to be inessential and eliminable? How are we so much as to understand the claim that even the Fool believes that that than which no greater can be conceived exists in the understanding? And how do we get from the Fool's *understanding* the words "that than which no greater can be conceived" to his *believing* that that than which no greater can be conceived possesses the property of existing in the understanding?

Following the earlier line of thought, it *seems* that the argument might go something like this:

1. (Even) the Fool has the concept of that than which no greater can be conceived.
2. (Hence) (Even) the Fool believes that that than which no greater can be conceived exists in the understanding.
3. No one who believes that that than which no greater can be conceived exists in the understanding can reasonably believe that that than which no greater can be conceived exists only in the understanding.
4. (Hence) (Even) the Fool cannot reasonably deny that that than which no greater can be conceived exists in reality
5. (Hence) That than which no greater can be conceived exists in reality.

While this argument does not look very compelling, it is plausible to claim that it would have seemed compelling to someone who failed to attend to the distinction which we have drawn between entertaining ideas and holding beliefs, and who was also a bit hazy on the distinction between the vehicles of belief and their contents. When the Fool entertains the concept of that than which no greater can be conceived he recognises that he is entertaining this concept (i.e., he believes that he is entertaining the concept of that than which no greater can be conceived -- or, as we might say, that the concept is in his understanding). Conflating the concept with its object, this gives us the belief that than which no greater

can be conceived possesses the property of existing in the understanding. Now, suppose as hypothesis for *reductio*, that we can reasonably believe that that than which no greater can be conceived possesses the property of existing only in the understanding. Ignoring the distinction between entertaining ideas and holding beliefs, this means that we when we entertain the idea of that than which no greater can be conceived, we entertain the idea of a being which exists only in the understanding. But that is absurd: when we entertain the idea of that than which no greater can be conceived, our idea encodes the property of existing in reality. So there is a contradiction, and we can conclude that, in order to be reasonable, we must believe that that than which no greater can be conceived exists in reality. But if any reasonable person must believe that that than which no greater can be conceived exists in reality, then surely it is the case that that than which no greater can be conceived exists in reality. And so we are done.

No doubt this suggestion about the interpretation of Anselm's argument is deficient in various ways. However, the point of including it is illustrative rather than dogmatic. In the literature, there has been great resistance to the idea that the argument which Anselm gives is one which modern logicians would not hesitate to pronounce invalid. But it is very hard to see why there should be this resistance. (Certainly, it is not something for which there is much argument in the literature.) The text of the *Proslogion* is so rough, and so much in need of polishing, that we should not be too quick to dismiss the suggestion that Anselm's argument is rather more like the argument most recently sketched than it is like the logically valid demonstrations provided by commentators such as Barnes, Adams, and Oppenheimer and Zalta.

Existence

Like many philosophically interesting notions, existence is at once familiar and rather elusive. Although we have no more trouble with using the verb ‘exists’ than with the two-times table, there is more than a little difficulty in saying just what existence is. Existing seems to be at least as mundane as walking or being hungry. Yet, when we say ‘Tom is hungry’ or ‘Tom is walking’, it may be news to those not in Tom's vicinity, whereas ‘Tom exists’ would be news to no one who knew Tom, and merely puzzling to anyone who did not. Again, we know what it is like to be hungry or to walk, but what is it like to exist, what kind of experience is that? Is it perhaps the experience of being oneself, of being identical with oneself? Yet again, we can readily indicate what is meant by Tom's walking, but surely Tom's existing is not something we can indicate to anyone. On the face of it, there would seem to be no way at all in which we can explain what existing is.

It may be tempting to think that ‘Tom exists’ means merely ‘Tom is real’. In fact, this could be distinctly appealing, for ‘real’ is what has been called an ‘excluder’ predicate, meaning thereby that it attributes nothing positive to Tom, but operates in a purely negative fashion simply to exclude Tom from being imaginary, mythical, fictional, and the like. To say that ‘exists’ meant ‘is real’ would be to say inter alia that it attributed nothing positive to Tom; and that would do much to relieve our frustration at being so fluent in our use of ‘exists’ despite having no idea of its attributing anything positive to Tom. It would be a relief to discover that ‘exists’ attributes nothing positive to him at all.

Unfortunately, this won't do; for among all the negatives that ‘is real’ might be applying to Tom would be not only ‘not imaginary’, ‘not mythical’, etc., but also ‘not nonexistent’. Now, suppose a seer predicted that in two years that a son would be born to Bill and Mary, and that he would be called ‘Tom’. When the prediction was finally fulfilled, we might imagine the seer announcing triumphantly ‘At last Tom exists, exactly as I predicted he would’. If ‘exists’ were an excluder like ‘is real’, then the seer could only be understood as excluding something from Tom; and in this case it would be non-existence. As said by the seer, therefore, ‘At last Tom exists’ could only mean ‘At last Tom is not-nonexistent’. And if he really were to mean that, we should be entitled to ask him just when Tom could ever have been said to be nonexistent, i.e. never to have existed. In fact, before he existed Tom could never even have been referred to, and hence at that time nothing at all could have been attributed to him, not even the property of being nonexistent. Promising as it may have seemed, therefore, ‘Tom exists’ is not to be understood simply as ‘Tom is real’.

Of course, the failure of attempts to understand ‘exists’ as ‘is real’ leaves plenty of room for other suggestions, each proposing to substitute one or more terms for ‘exists’, and thereby to show why our

original disquiet about it and existence has been sadly misplaced. If one thinks that ‘exists’ is readily dispensable in favour of some other (less troublesome) expression, then there will be no difficulty in dismissing the thought of there being some such property or attribute as existence. Alternatively, if one thinks that ‘exists’ is not to be dispensed with in this way, then one might be inclined to continue pursuing the puzzle of just what existence is.

It is probably now reasonably clear that the question of existence is inextricably intertwined with the question of ‘exists’. In some languages, the predicate ‘is’ does duty for ‘exists’, and even in English there are archaic uses of ‘is’ in that role. In discussing existence, therefore, we shall be much concerned also with the predicates ‘is’ and ‘exists’. In this regard, the predominant view on existence among contemporary philosophers of an analytic persuasion might be summarized in two theses, the first of which is the Frege-Russell distinction between four different meanings of ‘is’ - the ‘is’ of existence, of identity, of predication, and of generic implication (inclusion), as illustrated below.

- ‘Socrates is’, rendered in regimented language as ‘$(\exists x)(\text{Socrates} = x)$’.
- ‘Cicero is Tully’, rendered as ‘Cicero = Tully’.
- ‘Socrates is wise’, rendered as ‘Wise(Socrates)’.
- ‘Man is an animal’, rendered as ‘$(x)(\text{Man}(x) \rightarrow \text{Animal}(x))$’.

On this view, the different uses of ‘is’ entail correspondingly different meanings, so different in fact as to have nothing whatever in common. That is to say, they are casually ambiguous rather than being merely systematically ambigous or analogical, which would have been the case had their meanings been inter-related though without being univocal in any way - not even partially.

The second thesis commonly, though not universally, held by analytic philosophers might be summed up in the familiar dictum, ‘Existence is not a predicate’. More accurately, it should be written either as ‘Existence is not a (first-level) property’ or as ‘"Exists" is not a (first-level) predicate’. Before discussing current views on this and the earlier thesis, it will therefore be useful to be reminded of what some earlier philosophers have had to say about existence and, correlatively, about ‘is’ and ‘exists’ as verbs of being.

Earlier Views

Aristotle (384-322 BC): It is reasonably common ground among commentators that the Frege-Russell distinction is not to be found in Aristotle either in regard to the uses or the senses of 'is'. In so far as this applies to the existential and predicative uses, some have explained the former as being merely elliptical for the latter. Thus, 'Socrates is' would be merely elliptical for 'Socrates is a something or other', where the permissible substitutions for 'something or other' are any of Socrates' essential predicates. On this view, therefore, 'is' would be unambiguous because its use was always predicative, either explicitly as in 'Socrates is a man' or merely implicitly as in 'Socrates is'. Not only was the one sense being used, it was being employed with the same force in each case, namely, predicative.

For the preceding view, G. E. L. Owens claims support from Aristotle's saying that to be is to be something or other. Hintikka, however, reminds us of several passsages that would seem to conflict with the ellipsis hypothesis, among them the following.

> For it is not the same thing not to be something and not to be simpliciter, though owing to the similarity of language to be something appears to differ only a little from to be, and not to be something from not to be. (*De Soph. El.* 167a4-6)

Having undermined the ellipsis hypothesis to account for the lack of the Frege-Russell ambiguity in Aristotle, Hintikka suggests that what distinguishes different uses of 'is' in Aristotle is not a difference in sense but merely a difference in *force* - predicative, existential, and identificatory, respectively.

So far as distinct uses are concerned, there is no difficulty in finding prima facie examples of those distinguished by Frege-Russell. Ostensibly, 'Homer is' would seem to be a clear cut existential use, 'Socrates is a man' and 'Socrates is pale' predicative uses, and 'A man is an animal' a use of generic implication. As Aristotle understands them, however, these uses are not nearly so unrelated as they may appear to us. So far as the existential use is concerned, the earlier quotation is pertinent, for Hintikka interprets it as showing that the existential and predicative occurrences of 'is' are indeed related to each other as absolute and relative uses of the same notion. Although being used with existential force in the former but predicative *force*in the latter, 'is' has the same *sense* in both.

Just as 'is' can sometimes be used with existential force and sometimes with predicative force, it can also be used sometimes with predicative force and sometimes with the force of identity. Among predications, Aristotle distinguished between essential and accidental, with 'Socrates is a man' being an example of the first and 'Socrates is pale' an example of the second. In regard to essential predication but not to accidental predication, however, Aristotle takes 'is' to express identity. The former is to be understood as saying that Socrates is identically what 'to be a man' signifies, whereas in the latter he is not identically what 'to be pale' signifies. Similarly, in 'a man is an animal', a man is taken to be identical with what 'to

be an animal' signifies. So, just as the existential and predicative uses are not unrelated, neither are the predicative, identity, and generic implication uses unrelated. Being related to each other, the Aristotelian uses do not correspond to the four uses distinguished by Frege, since these are presented as being totally unrelated to each other.

As a final point about 'is', we might ask whether Aristotle recognized it as having one or two existential uses. According to Owen, he nowhere distinguishes between the two that Geach has called the 'actuality' and the 'there-is' uses.

Turning now from Aristotle on 'is' to Aristotle on existence. His conclusion in the *Metaphysics* was that for any entity to be was for it to be what it is, i.e. what it essentially is. If Socrates is essentially a man, then for Socrates to be would be for him to be a man. So, the *immediate* explanation of the reality of Socrates would be in terms of his being man. One might then ask what would explain the reality of being a man, with the answer being that it would stem from being an animal, and so on. At each point, the explanation of Socrates' existence would be in terms of what it is essentially. The point would be reached, however, when the explanation would be in terms of the *category* to which he belongs, which is substance. But, this could not be the *ultimate* explanation of his reality, since the same question could be asked of substance.

Now, if being were itself a genus, then substance (and indeed all the other categories) might belong to it, and the ultimate explanation of Socrates' existence could be in terms of being (existence). This option, however, is not available to Aristotle, since he insisted that being is decidedly not a genus. So, although for Socrates to be is for him to be what he is essentially, we can pursue that lead as long as wish, but will never reach the point at which being (existence) is part of the essence of any genus - even the ultimate one - to which Socrates belongs. As Aristotle recognized, Socrates' reality would ultimately have to be demonstrated.

This, however, should not be taken to be a tacit recognition that existence is some kind of ontological element additional to Socrates, for Aristotle draws no distinction between the being (existence) of entities and the being (occurrence) of events or the being (obtaining) of facts, and no one would suggest that the obtaining of a fact was some kind of ontological element additional to the fact. Thus, Aristotle provides an excellent example of someone who, unlike Frege, recognized that 'is' could indeed be predicated of individuals, but did not feel bound to accept any ontological implications therefrom.

Avicenna (980-1037): With Averroes (1126-1196), Avicenna was one of the pre-eminent Arabian philosophers of the middle ages. I mention him because, unlike Aristotle, he was insistent on existence being an ontological constituent that was quite distinct from essence. Essences, he noted, can be present either in things or (intentionally) in intellect: in the former case they are engaged in the reality of things, in the latter they are conceived of by intellect. Considered in se, however, they are in neither; for if, in themselves, they were in things, they could never be in intellect, nor vice versa. Considered in themselves, therefore, they are in fact pure possibility which, in Avicenna's view, is far from saying that they are nothing at all. Rather, they can be said to have a certain kind of existence (*esse essentiae*), albeit one very much inferior to actual existence (*esse existentiae*). The notion of esse essentiae was to reappear

later in Henry of Ghent (d. 1293) among others. Although it might seem to be a highly fanciful notion, it is hardly more fanciful than some haecceity theories which employ the same distinction, nor perhaps than some possible worlds theories either.

Whereas the immediate explanation of the actuality of Aristotle's substances lay in what they were essentially, that was not the case with Avicenna's essences for their status was that of the merely possible. They entered the realm of the actual only if existence (*esse existentiae*) happened (*accidit*) to them. Here, therefore, he has introduced a new element into the ontological scheme of things, an innovation that was later to earn him the reproach of his compatriot Averroes. The new element is existence, which Avicenna regarded as an accident, a property of things. In his view, it was sharply to be distinguished from essence. Such views had been quite foreign to Aristotle's scheme of things.

Aquinas (1225-1274): It was one thing to recognize existence as an ontologcal constituent of any existent, as Avicenna did, but quite another to accept some of his ancillary notions. While agreeing with Avicenna that a substance was to be distinguished from its existence, Aquinas rejected his view of the relation between the two. In particular, he had no room for the notion of esse essentiae and hence no room either for a realm of the purely possible, as Avicenna conceived essences in se to be. That is to say, he did not think there was anything (such as a purely possible essence) to which existence might be said to accrue. For just that reason, existence could not be an accident of substance, since accidents do in fact accrue to something. And, if it were not an accident, it could not be related to substance in the same way as accidents are: it could not *inhere*in a substance. Having said this, however, Aquinas freely admitted that existence was indeed accidental to substance. This was not to contradict himself, since it meant merely that it was a contingent matter whether something existed or did not. It did, however, place the onus on Aquinas to explain just what the relation might be between an entity and its existence, if the latter were not an accident.

Moving now to the linguistic plane, it has to be said that Aquinas' views on the verb ‘is’ are scattered throughout his many works, but have fortunately been assembled and inter-related in an illuminating study by Hermann Weidemann. Like Aristotle, Aquinas had no difficulty in distinguishing the existential use of ‘is’ from the ‘is’ of identity and the ‘is’ of predication. Having said that, however, it has also to be said that he regarded the last two as closely related, with the predicative use being marked by an element of identity, and the identity use being marked by an element of predication. The predication ‘Socrates is pale’, for example, was understood to be proposing the identity of Socrates with something pale, and ‘Socrates = Socrates’ was understood to be proposing the inherence in Socrates of the property of being Socrates. Unlike the Frege-Russell thesis, Aquinas did not regard these three uses of ‘is’ as being totally unrelated.

A crucial difference between Aquinas and Avicenna, however, lies in the distinction he draws between two existential uses of ‘is’. In one of them, ‘is’ is taken to express the being of whatever falls under the Aristotelian categories, whether it be of substance or of any of the accidents. As used in this way, ‘is’ refers to that by which something is actual. In the second existential sense, however, it expresses the truth of a proposition. Following Geach, these two existential uses might be called the ‘actuality’ and the ‘there-is’ uses respectively. Interestingly, the actuality use is said to occur not only in such propositions as

'Socrates exists' but , surprisingly to modern ears, in such propositions as 'Socrates is a man'. Indeed, it occurs in any of those predicates that respond to the question '*Quid est .....?*' ('What is ....?'), and which Aquinas calls substantial. It is in this use that 'is' is taken to express the being of whatever falls under the Aristotelian categories.

In its there-is use, 'is' is said to express the truth of a proposition, and to answer the question '*An est...?*' ('Is there any such thing as ....?'), and which Aquinas calls accidental. In these cases 'is' has the dual function not only of linking subject and predicate, but also of expressing the truth claim that is being made thereby.

As for the ambiguity of 'is', Aquinas' position would seem to be:

1. There is systematic ambiguity between the uses of 'is' to express the actuality of what falls under any of the ten categories.
2. There is no ambiguity at all between the actuality use of 'is' and its use in substantial predication: they are the same.
3. There is no ambiguity at all between the there-is use of 'is' and its use in accidental predication: they are the same.
4. There is systematic ambiguity between the actuality and the there-is senses of 'is', and this is founded on the supposition that the truth of what we say is founded upon the actual existence of what we talk about.

Hume (1711-1776): Aquinas' distinction between essence and existence was not long unchallenged even among the Scholastics, being rejected early by Scotus and much later by Suarez. Descartes and Leibniz also denied it, and Hume took the same view, though for reasons peculiar to his own impression-based epistemology. Thus, he argued that 'the idea of existence must either be derived from a distinct impression, conjoined with every perception or object of our thought, or must be the very same with the idea of the perception or object'. (*Treatise of Human Nature,* Bk.I, Part II, sect. vi) There being nothing to indicate the presence of any impression at all that is 'conjoined with every perception or object of our thought', he concludes that there is no distinct impression from which the idea of existence is derived. Rather, it is 'the very same with the idea of what we conceive to be existent'. Any one dissenting from this, suggests Hume, has the task of indicating just what is the distinct idea from which the idea of existence derives.

Hume's contention that the idea of existence 'makes no addition' to the idea of any object was to be reaffirmed in Kant

Kant (1724-1804): The following familiar passage clearly indicates how closely Kant is aligned with Hume's conclusion about existence.

> By whatever and by however many predicates we may think a thing - even if we completely determine it - we do not make the least addition to the thing when we further

> declare that this thing is. ... If we think in a thing every feature of reality except one, the missing reality is not added by my saying that this defective thing exists. (Critique of Pure Reason, B628)

Earlier he had reminded us that ‘the real contains no more than the merely possible. A hundred real thalers do not contain the least coin more than a hundred possible thalers.’ Thus, he is able to claim that ‘"being" is not a real predicate’, though he does allow that it is a logical predicate, for ‘anything we please can be made to serve as a logical predicate’.

That being so, just what role does ‘is’ play in such propositions as ‘God is’ or ‘God is omnipotent’? In both, says Kant, its role is simply to posit (*setzen*) the subject. In the former, it posits the subject (God) ‘in itself with all its predicates’; in the latter it posits the predicate in relation to the subject (God). The ‘is’ in the former and the ‘is’ in the latter seem to be merely two uses of the one notion - in some respect reminiscent of the ‘ellipsis’ interpretation of Aristotle's uses of ‘is’. In any case, this position is clearly contrary to the ambiguity of ‘is’ that was later to be espoused by Frege.

Frege (1848-1925): Frege regarded existence as a second-level concept. In explanation of this, it has to be remembered that, in his terminology, concepts are not intentional entities, as one might have surmised, but are no less ontological items than are objects. Just as objects are the referents of singular terms, so are concepts the referents of predicates, which might also be called ‘concept expressions’. Some predicates are attached to singular terms to form a proposition and hence say something about the objects to which those terms refer, e.g. in ‘Socrates wise’. These are called first-level predicates or concept expressions, and refer to first-level concepts, e.g. being wise. Other predicates are attached to first-level predicates to form a proposition and hence say something about the concept to which the first-level predicate refers. They are second-level predicates, and refer to second-level concepts. A case in point would be ‘Wisdom (or being wise) is rare’, in which the predicate ‘is rare’ would refer to a second-level concept, being rare. There can of course be still higher-level predicates with their correlative concepts to which they refer.

In saying that existence was a second-level concept, Frege was also denying not only that it was a first-level concept but also that ‘exists’ was a first-level predicate, contrary to what might appear to be the case in propositions like ‘Socrates exists’. Interestingly, one of his reasons for opposing a first-level use was similar to the paradox that some contemporaries insist is generated by negative existential propositions like ‘Socrates does not exist’. The putative paradox is said to arise because ‘does not exist’ could be said of Socrates only if he did in fact exist. In his ‘Dialog mit Puenjer ueber Existenz’ Frege argued that, in the proposition ‘Leo Sachse is’, nothing is being attributed to Leo Sachse. Puenjer had proposed that the ‘is’ be understood as elliptical for ‘is something that can be experienced’, to which Frege replied that if ‘*A* is not’ were to be understood as ‘*A* is not an object of experience’, it would be self-contradictory. Why? Because on the one hand *A* certainly is an object of experience, whereas on the other hand *A* is being said not to be an object of experience: it both is and is not an object of experience. Since the same point could be made no matter what was substituted for ‘is’ in ‘Leo Sachse is’, the role of ‘is’ in that proposition could not be that of a first-level predicate.

Given that ‘is’ or ‘exists’ are precluded from being first-level predicates, just how are affirmations of

existence to be understood? According to Frege, ‘Affirmation of existence is in fact nothing but the denial of the number nought’ (*Die Grundlagen der Arithmetik*). This means, as he says elsewhere, that existence is ‘a property of a concept’: it is a second-level property (or concept). As for the predicate ‘exists’, it is therefore understood to be attached to a first-level predicate, and hence is itself not a first-level predicate but a second-level one. More concretely, ‘Leo Sachse is’ should, in Frege's view, be rendered as ‘(∃x)(x = Leo Sachse)’ or, in non-symbolic terms, as ‘There is at least one thing that is identical with Leo Sachse’. Thus understood, it is clear that nothing is being predicated of Leo Sachse. Rather, something is being said about the property (or concept) of being identical with Leo Sachse: we are being told how often that particular property is instantiated, namely, at least once. And, of course, ‘at least once’ is ‘the denial of nought’.

Issues Raised by the Historical Survey

The foregoing brief and selective historical survey enables us to distinguish a number of questions not only in regard to the verbs ‘is’ or ‘exists’ but, on the ontological level, in regard to existence. In regard to ‘is’, it has been generally agreed that it admits of various uses. Apart from the ‘ellipsis’ interpretation of Aristotle which admits of only one use, the differences have not been about whether there are many uses of ‘is’, but about just how many there are. The main difference, however, has been about senses rather than uses: is the one sense being used with different forces, or are there as many senses as there are uses? This is not an idle question, for it can never be assumed that different senses correspond to different uses. Moreover, even if the senses do differ, it cannot be assumed that they will be casually ambiguous, for they might be merely systematically ambiguous, as Aristotle conceives some of the predicative uses of ‘is’ to be.

Have we to choose between the Frege-Russell treatment of ‘is’, the Aristotelian treatment, and perhaps some other? According to Hintikka, we can both have our cake and eat it since, as he argues, there can be more than one correct way of dealing with ‘is’. He reminds us that the Frege-Russell ambiguity need have no part in game-theoretical semantics. He even argues that we can say not only ‘that Aristotle's procedure is free from any taint of fallacy; he may even have been a better semanticist of natural languages than Frege and Russell ever were.’ (‘The Varieties of Being in Aristotle’)

Not all questions about the use of ‘is’ can be resolved so eirenically, and the question of whether there is a first-level use is one of them. Although Hume and Kant accept predicative uses, it is not clear that they would accept existential ones. The three A's - Aristotle, Avicenna, and Aquinas - would seem to accept both. Frege, too, would recognize both. But, whereas Aquinas recognizes two existential uses, Frege accepts only the there-is use. For Frege, the existential use of ‘is’ or ‘exists‘ is invariably as a second-level predicate. For Aquinas, there is a first-level use in addition to the second-level one. Geach, too, argues for a first-level use of ‘exists’ as do Parsons and Zalta, though on different grounds.

If there were a straightforward a priori way of showing that Frege was right, we should be absolved from having to consider attempts to undermine his view. Unfortunately, things are not so simple for, although a case can be made out for two existential uses, its cogency is still much disputed. The case turns on the

possibility of showing not only that ‘is’ or ‘exists’ can sometimes be predicated of individuals but also why the there-is sense cannot substitute for it.

Where the discussion would go from here is something that depends on whether the case for two uses is thought to prevail. If it does, then a number of additional issues would have to be addressed, for if ‘is’ or ‘exists’ were a first-level predicate then, like all predicates, it would have a reference which in this case would be existence. And, if we describe a property in the wide sense as whatever would be attributable to something by a predicate, then existence would be a property of individuals, thereby undermining the widely held dictum ‘Existence is not a predicate’.

Now, if existence were a property of individuals, then it would seem legitimate to join Hume and Kant in asking just what it adds to individuals. Since their question is posed merely rhetorically, it would presumably be satisfied by existence being simply a Cambridge property, for the distinguishing mark of Cambridge properties is precisely that they add nothing to individuals. The immediate task confronting proponents of the actuality use of ‘is’ or ‘exists’ would be to determine whether the existence to which they were committed was in fact a real property or a Cambridge one.

If the contention were that it was real, the Hume-Kant question would pose a pressing problem, albeit not necessarily a decisive one. It would be decisive only if existence were an accident of individuals, only if its relation to individuals were what Aristotle would call one of inherence. According to the notion of a property which I introduced earlier, a property is whatever is attributed to something by a predicate. This notion, however, is neutral as to the kind of relation a property would have to the subject to which it was attributed. In particular, it does not imply that what is attributed should be an accident of the subject. Moreover, even in the Aristotelian ontology, not everything that was attributed to a subject had to be an accident. Hence, if defenders of existence as a first-level property wished to rebut the Hume-Kant objection, they would have to establish that, contrary to Avicenna, existence was not an accident of individuals. If that proved impossible, they might be forced to surrender their claims, and accept that Frege was right after all about the single existential use of ‘is’.

Arguments for the Fregean View of ‘Exists’

In the heyday of logical positivism Alfred Ayer confidently asserted that, if ‘exists’ were a predicate or existence a property, ‘it would follow that all existential propositions were tautologies, and all negative existential propositions were self-contradictory’. No need to distinguish between singular and general existential propositions, nor to make any distinction between kinds of general existential propositions. No matter where it occurred, ‘exists’ was not a predicate.

Few would take that view today. Many would hold that ‘exists’ is indeed a predicate, but would hasten to add some qualification - either that it was ‘peculiar’, had ‘special characteristics’, was ‘redundant’, was a second-level predicate, of that it was a metalinguistic predicate. The dominant view is that ‘exists’ is a second-level predicate, and it is grounded largely on the contention that to admit ‘exists’ as a property of individuals would lead on the one hand to the absurdity of regarding existence as a property, and on the

other hand to the paradox supposedly generated by negative existential propositions.

As to the first, presumably it is thought that if existence were a property, then non-existence would be one also. And that would seem to give rise to the ludicrous situation described by David Londey who invited us to ‘reflect on the absurdity of a farmer who daily inspected his flock with the aim of sorting the existing from the non-existent ones - searching for the stigmata of existence’. It would give rise also to C.J.F. Williams' enquiry as to whether, if told that blue buttercups did not exist, he would ‘have felt obliged to examine several specimens of blue buttercup before concluding that none of them exist, that as a variety blue buttercup lacks existence’. Hume and Kant would have nodded approvingly.

As to the paradox generated by negative existential propositions, it arises in this way. If ‘exists’ were a predicate, then its negation (‘does not exist’) should be a predicate also. But if ‘does not exist’ were a predicate, then in ‘Dragons do not exist’ it would be predicated of dragons only if dragons existed. And similarly for all negative existential propositions; paradoxically, if it is to be predicated at all, ‘does (do) not exist’ can be predicated only of what does exist.

Nor do singular propositions like ‘Socrates does not exist’ seem to fare any better than general ones like ‘Dragons do not exist’. Despite his demise, there are of course many true predications that can still be made of Socrates, e.g. that he was a philosopher, that he was Greek, and the like. But all of these were true of him while he was yet alive. If, however, ‘does not exist’ were true of him, it could be true, paradoxically, only after there was any Socrates for it to be true of. Again, as a variant formulation of the paradox, it might be argued that if ‘exists’ were a predicate of individuals, it would be true of everything. In that case, ‘does not exist’ would be true of nothing: neither ‘Socrates does not exist’ nor any other singular negative existential proposition could be true. In that case, however, ‘does not exist’ could not be a predicate. But, if ‘does not exist’ could not be a predicate, its negation (‘exists’) could not be a predicate. The assumption that ‘exists’ *is* a first-level predicate has therefore led to the paradoxical result that ‘exists’ *cannot* be a predicate. So, singular negative existential propositions are no less paradoxical than are general ones.

It is argued that the paradox could be avoided by treating ‘exists’ as something other than a first-level predicate. In doing so we should also remove perhaps the strongest ground for regarding existence as a property. And thus in one move we should avoid putative paradox and absurdity alike.

We have already seen how Frege succeeded in doing exactly that. Russell did the same with his similar view of existence as a property not of things but of propositional functions, a proposal made in connection with his treatment of definite descriptions. As such, its immediate application is only to general existential propositions, but not to propositions like ‘Socrates exists’. Since Russell regarded ‘Socrates’ as merely a disguised description, he himself would have rejected this restriction. But for those who do not share his view on proper names, the restriction could be overcome by adopting Quine's proposal that ‘Socrates exists’ be reparsed as ‘$(\exists x)(x = \text{Socrates})$’. Quine takes the further step of eliminating the predicable ‘= Socrates’ in favour of one that contains no proper name, viz. the predicable ‘socratizes’. Thus, ‘Socrates exists’ would be understood as ‘$(\exists x)(x$ socratizes$)$’, or ‘The property of socratizing is instantiated at least once’. If Quine is correct, then we have a means of handling existential

propositions that treats them neither as tautologies nor as contradictions, yet without the difficulties that would arise if ‘exists’ were a predicate. Further advantages are claimed for it. Basically, singular existential propositions would be treated in the same way as general ones. Moreover, there would be no need for multiple senses of ‘exists’. Indeed, ‘exists’ itself would be made redundant, being replaceable by the more general apparatus of quantifiers and identity. And, finally, there would be no need to recognize, as the early Russell did, entities that subsist in addition to those which exist. Thus, the theory seems not only to solve the problem, but to do so with an economy that enhances its appeal.

Criticisms of the Fregean View

Questions have been raised not only about the validity of the paradoxes and absurdities allegedly generated by accepting ‘exists’ as a first-level predicate, but also about the Quinean treatment of propositions like ‘Socrates exists’. As for the paradoxes and absurdities, it might be argued that they stem not from allowing existence to be a property, but from allowing non-existence to be one. Only by thinking that non-existence was some kind of real property would any sheep-farmer be led to the absurdity of inspecting his flock ‘with the aim of sorting the existing sheep from the non-existent ones’ or would anyone feel inclined to ‘examine several specimens of blue buttercup before concluding that none of them exist’. Only if non-existence were a real property (rather than merely a Cambridge one) would it seem paradoxical that ‘does not exist’ could be true of Socrates only after there was any Socrates for it to be true of.

It might seem strange, therefore, that the blame has been laid on treating existence as a real property of individuals, when it should surely have been laid on treating non-existence as one. Why deny that existence is a property, when it was necessary only to deny that non-existence was one? Perhaps the answer lies in the understandable but mistaken belief that the two denials are inseparable, and so there could be no denying non-existence to be a real property of individuals without denying existence to be one also. After all, if properties are what predicates stand for, how could it be said that ‘exists’ stood for a property, but that ‘does not exist’ did not? If we accept existence as a property, are we not bound also to accept non-existence as one? Clearly, these suggestions rest on two assumptions that need to be tested:

1. that ‘Socrates does not exist’ contains a negative existential predicate,
2. that a negative existential predicate stands for a real property.

In regard to (1), although ‘does not exist’ is a grammatical predicate in ‘Socrates does not exist’, it does not follow that it must also be a logical one. We need to recognize the possibility of construing the proposition as having the logical form of ‘It is not the case that (Socrates exists)’. In that case, what is predicated (though not asserted) of Socrates would be simply ‘exists’ (and not ‘does not exist’); and what would be asserted is that it is not the case that Socrates exists. On such an analysis of singular negative existential propositions, ‘does not exist’ would not be a predicate, and nor therefore need non-existence be a property of any kind.

The distinction being employed above is one between internal or predicate negation on the one hand and

external or propositional negation on the other. In both cases something is said about an individual, namely, Socrates; the former says that non-existence is had by Socrates, and the latter denies that existence is had by Socrates. It is true that first-order predicate logic is so constructed as to admit no such distinction, but that does not mean that there is no such distinction tout court. Consider the proposition '*a* is not moral' which may mean either of two things. It may mean that *a* has the 'property' of being non-moral; alternatively, it may simply be denying that *a* has the 'property' of being moral. Internal negation ('*a* (is not moral)') is being used in the first case, but external negation ('It is not the case that (*a* is moral)') in the second. If, therefore, the distinction between internal and external negation were one without a difference, those two renderings should mean the same. Yet, that is just what they do not mean; for the first is to be taken as '*a* is immoral', but the second as the quite different '*a* is either immoral or amoral'. The distinction cannot therefore be dismissed as a 'distinction without a difference'.

It is therefore not a matter of indifference whether 'Socrates does not exist' is rendered as '(Socrates) does not exist' or as 'It is not the case that (Socrates exists)'. Because it is the former but not the latter that gives rise to problems, the latter is clearly to be chosen. So, it remains true that 'Socrates does not exist' would not contain 'does not exist' as a logical predicate, and that existence could be recognized as a real property without the embarrassment of having to recognize non-existence as well.

It is worth noting that the paradox could be argued not to arise even if the negation in 'Socrates does not exist' were to be intemal rather than external. First, however, we need some criterion for deciding when individual *a* could lack some property *F* only by having another property non-*F* correlative to the one it lacks. Well, let us consider this not in regard to existence but in regard to the property red. The question therefore is whether the absence of redness from something which could be red must bespeak the presence of a property correlative to red. Certainly, if *a* were a piece of wood then it could lack redness only if it had some colour or colours other than red - be it brown, cream, fawn, or whatever - all of which are properties. That does not settle the question, however, since the result would be very different if *a* were not a piece of wood but a piece of glass.

Now, although glass is like wood in being something that could be red, it is also unlike wood in that its failure to be red does not mean that it is any colour at all: it may be quite colourless. To say that it is non-red, therefore, is not to say that it has any correlative property. Reflecting on this example, it is not difficult to see that lack of a property *F* bespeaks the presence of a correlative property non-*F* only if *F* and non-*F* are understood as determinates of a common determinable. Thus, if red and non-red were related as differentiae of the determinable property being coloured, red could be lacking in an *a* that was coloured only if some determinate of colour were present in *a*

The relevance to the discussion of non-existence is fairly clear. If lack of existence in *a* (which had existed) were to bespeak the presence in *a* of non-existence as a real property rather than as merely a Cambridge one, existence and non-existence should be related to some real property just as red and non-red would have had to be related to the property of being coloured. For convenience, let us call this determinable property '*E*'. Then, just as red and non-red would have had to be understood as coloured red and coloured other than red, so existence and non-existence would have to be understood as being *E* in an existential way and being *E* in a non-existential way.

Thus, whether *a* existed or did not exist, it would have some form of being: it would be *E*. But that is false. Hence, even if ‘Socrates does not exist’ were to contain the predicate ‘does not exist’, the property stood for by that predicate could at most be a Cambridge one; and Cambridge properties can be acquired even by individuals that do not exist at the time. Consequently, no paradox would arise from ‘Socrates does not exist’. This has already been demonstrated for the case where the negation was taken to be external to the proposition; it has now been demonstrated for internal negation as well.

To sum up. It has been argued that, no matter whether the distinction between internal and external negation in this context were accepted or rejected, the result would be the same. In neither case would we be committed to Socrates acquiring any property whose acquisition is conditional upon Socrates existing at that time. In neither case, therefore, would ‘Socrates does not exist’ generate the paradoxes or absurdities which would make it impossible to count ‘exists’ as a first-level predicate and existence as a real property of individuals.

Turning now to the questioning of Quine's construal of ‘Socrates exists’ not as ‘Socrates has (the property) existence’ but as ‘The property of socratizing is instantiated at least once’. This has the appearance of dispensing with the use of proper names and dispensing also with the recognition of what proper names typically refer to, viz. individuals. It can be argued, however, that this is simply an illusion, because the notion of instantiation in fact makes no sense except in relation to what is instantiated (a property) and what it is instantiated *in* (an individual). Or, more technically, instantiation is akin to a second-level function that Frege called the ‘application’ of a function to an object: a second-level function is inconceivable except in terms of what are stood for by the expressions filling its two gaps. So, individuals cannot be eliminated by introducing the notion of instantiation, for that very notion is itself intelligible only in terms of individuals. On this view, therefore, ‘Socrates exists’ is logically more basic than the proposition ‘$(\exists x)(x$ socratizes)’ that has been advanced to dispense with it. (It might be replied that this objection would fail to impinge on Quine's position, since he eschews properties in favour of classes. On the contrary, the classes which are substituted for properties are no more intelligible without the notion of an individual than are the properties they are supposed to replace.)

Arguments for the Two-Sense Use of ‘Exists’

To accept the Fregean view of ‘exists’ as a second-level predicate is to accept that ‘exists’ can in fact always be rendered by ‘instantiates’. Of course, there are many cases where it can indeed be understood in just that way. However, although ‘Elephants exist’ can be understood as ‘The property of being an elephant (or the species elephant) is instantiated at least once’, there are grave difficulties about regarding ‘Socrates exists’ as ‘Socrates is instantiated at least once’. The problem is that individuals are just not the kind of thing that ever could be instantiated. Rather than being themselves instantiable they are the kind of thing in which instantiations occur, e.g. wisdom is instantiated in Socrates, but Socrates himself cannot be instantiated in anything. Russell and Quine would certainly have recognized this, and each in his own way attempted to get round it, though with questionable success.

The two-sense theory, in effect, accepts that there is no way round it. Thus, while not denying that ‘exists’ does have a second-level use, it insists on there being a first-level use as well, one in which ‘exists’ is not to be understood in terms of ‘instantiates’. The theory's claim for different uses of ‘exists’ in ‘Socrates exists’ and ‘Elephants exist’ is in some respects like different uses for ‘disappear’ in ‘Jack the Ripper disappeared’ and ‘Dodos disappeared’.

Now, there are at least two ways of arguing for the theory, the first of which is explained briefly by Hintikka, as quoted below.

> If we take an individual in the actual world and assign to it a predicate which involves existence or nonexistence in some other world, surely we ought ... be able to take "a merely possible individual", i.e. a denizen of some other world, and attribute to it predicates definable in terms of its actual existence, maybe the "predicate of (actual) existence itself". Basically, it seems to me, that this argument is unanswerable. (‘Kant on Existence and Predication’, p.255)

His view of possible individuals is reminiscent of Avicenna's claim that possible essences do indeed have a certain kind of being, namely, esse existentiae. And, being aware that his argument might be criticized for supposing that there could be individuals that have never existed - merely possible individuals -, Hintikka attempts to forestall it by contending that it is ‘based on an unrealistically narrow view of how our language actually functions’. That might be a compelling consideration if the criticism concerned the use of proper names for these individuals, for in such circumstances the names would be no more exceptional than are names for fictional individuals. The objection, however, is not to the use of names, but to the apparent supposition that merely possible individuals have as much claim to be accepted as individuals as do actual ones. In other words, actual and merely possible individuals would be two kinds of individual, no less than Labradors and Beagles are two kinds of dog. On the contrary, merely possible individuals (and fictional individuals as well) have no more claim to be regarded as a kind of individual than rocking horses have to be regarded as a kind of horse.

A more promising argument is one that draws upon an insight of Peter Geach, and would run as follows:

- What can be predicated of a kind differs absolutely from what can be predicated of an individual.
- But ‘exists’ is predicated both of individuals and of kinds.
- Therefore, ‘exists’ has two senses, one as predicated of individuals, the other as predicated of kinds.

In regard to the first premiss, although there are two ways in which a predicate might be conceived of as being applicable to both kinds and individuals, it is not difficult to show that neither is tenable. One way would be for a second-level predicate to be said of both individuals and kinds, the other for a first-level predicate to be said of them. In regard to the first alternative, we must be clear as to precisely what kind of expression can be said of what the first-level predicate refers to (e.g. a kind, or Fregean concept). If we consider the proposition ‘$(\exists x)(x \text{ is } F)$’, the first level predicable is ‘......is *F*.’ The second-level predicate

attached to it is, however, not simply '(∃*x*)', but '(∃*x*)(*x*......)'. If we now ask whether the second-level predicate could equally well be attached not only to a first-level predicable but to a proper name, it is clear that it could not. The bound variable, which filled the gap in '......is *F*', has nowhere to go when '......is *F*' is replaced by a proper name. The expression that results from such a combination is therefore not even a closed sentence. Nor does anything better come of the second alternative mentioned above. If '......is *F*' and '......is *G*' are two first-level predicables, then the result of combining them would be '(......is *G*) is *F*' or '(......is *F*) is *G*'. Once again, neither combination would be even a closed sentence, as the gap would be filled neither by a bound variable nor by a proper name. Thus, it follows that no predicate, whether of first-level or of second-level, could be said both of individuals and of kinds. And that would establish the first premiss.

The second premiss can be argued for in two ways - either by contrasting singular existential propositions with one kind of general existential proposition, or by contrasting two kinds of general existential proposition. As an example of a singular proposition in which 'exists' is predicated of an individual, one might be tempted to suggest 'Socrates exists', were it not for oft-voiced protests of its not being 'usable outside philosophy'. Rather than resist that claim, therefore, it would be better to employ an example that unquestionably is usable outside philosophy, viz. 'Socrates no longer exists'. This should be understood as 'It is no longer the case that (Socrates exists)', which clearly involves use of the proposition 'Socrates exists'. T? ?e?ning now to the second-level uses of 'exists', they are both numerous and non-controversial. 'Men exist' is a case in point, for it may often be rendered as '(∃*x*)(*x* is a man)', thus showing it not to be about any individual but, rather, about the property of being a man; for it says that being a man is instantiated at least once. Hence, 'Socrates no longer exists' and 'Men exist' provide the evidence necessary for the premiss that 'exists' is predicable both of individuals and of kinds; for the only way of eliminating the difference between them is to reparse 'Socrates' as a predicable after the manner of Quine, and that has already been shown to be unacceptable.

There is, however, a second way of proving the minor premiss, and this even without recourse to any singular existential propositions. It can be done by showing that not even all general existential propositions are about kinds, but that some are about individuals. As an example of the two kinds of general existential proposition, consider the occurrences of 'elephants exist' below.

a. 'Elephants exist, but mermaids do not.'
b. 'Elephants exist, but dinosaurs do not.'

As will now be shown, 'exists' in (a) is being said of the property of being an elephant, not about individual elephants, whereas in (b) it is being said of individual elephants, not about the property of being an elephant. These claims can readily be substantiated. Since, in (a), 'Elephants exist' is being contrasted with 'Mermaids do not', the sense in which 'elephants' is being used will be the same as that in which 'mermaids' is being used. Now, 'Mermaids do not exist' makes sense only if it means that all predications of the form '*x* is a mermaid' are false. And it cannot mean that any proper name which turns '*x* is a mermaid' into a true statement will turn '*x* does not exist' into a true one, the simple reason being that there are no non-fictional proper names available for substitution in '*x* is a mermaid'. Hence, 'mermaids' is being used to refer to the property of being a mermaid, not to individual mermaids. Thus,

‘elephants’ in the accompanying clause must refer to the property of being an elephant. One might try to escape that conclusion by suggesting that a fictional name might well be substituted for ‘*x*’, as of course it might. That, however, would do nothing to alter our conclusion since fictional individuals are not concrete individuals any more than rocking horses are horses. So, there are no grounds for saying that non-fictional proper names can be substituted in ‘*x* is a mermaid’, and so no grounds for saying that ‘mermaids do not exist’ can be equally about kinds or about concrete individuals.

In (b), on the contrary, neither do ‘elephants’ refer to the property of being an elephant nor ‘dinosaurs’ to the property of being a dinosaur. If they did, the proposition would not only be false, but the ‘but’ would be quite misleading since there would be no point of contrast between the first and second clauses. The only way to retain that contrast is for ‘elephants’ and ‘dinosaurs’ to refer to individuals. So, in (b), ‘Elephants exist’ is a general existential proposition that is about individuals, as contrasted with the same clause in (a) which is not about individual elephants at all but merely about the property of being an elephant. It is of some interest to have noted that the first-level use of ‘exists’ is not restricted to singular propositions, as might have been supposed, but can occur in (some) general propositions as well.

The second premiss - that ‘exists’ is predicable of both kinds and of individuals - has therefore been supported in more than one way way. From it and the major it would follow that ‘exists’ has two senses, one as predicable of individuals, the other as predicable of kinds, and which have been called by Geach the actuality and there-is senses respectively.

Arguments for Distinguishing ‘Exists’ from ‘Is’:

The two-sense theory has been concerned with the the role of ‘exists’ as a predicate of concrete individuals among which it has certainly not included numbers, universal properties, propositions, and such intentional entities as Pegasus, Sherlock Holmes, unicorns, round squares, and golden mountains. The inclusion of precisely those entities has, however, been a feature of the work of those like Terence Parsons and Edward N. Zalta who draw some of their inspiration from Meinong. Their common aim is to provide a logic - an intensional logic - which will explain the apparent failure of one or other principles of non-intensional logic in certain contexts. Expressed otherwise, their goal is to ‘explain how commonsense non-existence claims of natural language mean what they seem to mean and have the truth-values, logical form, and entailments that they seem to have’. (Zalta, p.103) For our purposes, these views are notable for introducing a further consideration for recognizing the use of ‘exists’ as a first-level predicate. As we shall see, however, the price of achieving a logic that is more faithful to the ways in which we ordinarily talk is to embrace ontologies that are rather more distant from the ways in which we ordinarily think.

Parsons' system has three basic features:

- *The distinction between nuclear and extranuclear predicates and likewise between their corresponding properties.* As examples of nuclear predicates we are offered ‘is blue’, ‘is tall’, ‘kicked Socrates’, ‘was kicked by Socrates’, ‘kicked something’, ‘is golden’, ‘is a mountain’.

Examples of extranuclear predicates include ‘exists’, ‘is mythical’, ‘is fictional’, ‘is possible’, ‘is impossible’, ‘is thought about by Meinong’, ‘is worshipped by someone’, ‘is complete’. As critics have noted, the distinction is far from transparent.

- *The correlation between non-empty sets of nuclear properties and genuine objects.* Objects are correlated with (but not identified with) sets of nuclear properties - real objects with complete sets, and non-existent sets with incomplete sets. A set is complete if, for any nuclear property, an object has that property or its negation. Otherwise, a set is incomplete. Critics consider this distinction, too, to be less than obvious. Moreover, Parson's stipulation that no two objects have exactly the same nuclear properties might suggest that he adheres to the suspect Identity of Indiscernibles.
- *The distinction between objects that **are** and objects that **exist**.* The predicate ‘exists’ is said to be applicable to ‘all the ordinary [concrete] objects that we normally take to exist’. (p.11) Parsons recognizes objects that would not normally be regarded as concrete, namely, golden mountains, winged horses, round squares, Pegasus, and Sherlock Holmes. These objects are said not to exist, but merely *to be*. Thus, of objects like tables we can say both ‘Tables exist’ and ‘There exist tables’. Of other objects we can say merely that there *are* such things, e.g., ‘There are unicorns’. Such objects are said to be *non-existent*. In virtue of the distinction between existing and merely being it is then possible to say without any kind of contradiction, or even paradox, ‘There are unicorns, but they do not exist.’ This makes perfectly good sense because, as Parsons uses the terms ‘is’ and ‘exist’, what exists does not exhaust what there is. (p.5)

Obviously, this is directly at odds with the Frege-Russell-Quine one-sense theory, in which what exists is precisely what there is. Less obviously, perhaps, and despite its distinction between what exists and what there is, it sits uneasily with the two-sense theory as well, for that theory presupposes an absolute distinction between individuals and properties, a distinction which is blurred by Parsons. Even if we allow that his *existing* objects are not mere bundles or sets of properties, it is not obvious how the same can be said of his non-existent objects. He needs therefore to tell us in what sense the golden mountain is anything more than a set of properties, namely, of being golden, of being a mountain, and of being existent. If it is nothing but such a set, it is no more concrete than are properties; and these he has classed as abstract. Contrary to his declared aim therefore, his theory would seem not to be one about concrete objects after all. But, if it is not about concrete objects, ‘is existent’ cannot be a first-level predicate - unlike ‘is golden’ and ‘is a mountain’. But, then, what becomes of the claim that existence and being existent are two kinds of being? They can hardly be two kinds of being if the former is a first-level property while the latter is merely a second-level one.

Zalta, comparing his own theory with that of Parsons (p.134), draws attention to its ‘explanatory elegance’ in replying to Russell's three objections against Meinong. Whereas each of Parsons' replies employs a different strategy, each of Zalta's replies employs just the same two hypotheses, viz:

1. That ‘is’ can also be read as ‘encodes’.
2. That descriptions of the form ‘The $G_1, \ldots, G_n$,’ when said in a Meinongian way, have readings in which they denote A-objects that encode the properties $G_1, \ldots, G_n$.

The notions of A-objects (abstract objects) and of encoding are central to his theory, and need now to be explained.

One of the problems with intentional objects is that they themselves do not seem to have the properties that they represent - the object which represents blue is not itself blue. Although this was a point to which Brentano adverted in the last century, its history extends as far as the middle ages and beyond to Aristotle. The mediaevals resolved their difficulty by suggesting that the identical form may have two modes of existence, physical and intentional. For example, the identical form or forms had materially (physically) by Bucephalus would be had immaterially (intentionally) by the person perceiving him. All the forms (substantial and accidental alike) existing physically in Bucephalus would exist intentionally in whoever perceived him.

To deal with the same problem, Zalta distinguishes not between physical and intentional *existence* but between physical and intentional *objects*. Physical objects are said to be concrete and to *exemplify* various properties. Intentional objects, on the contrary, are abstract, a term which Zalta seems to regard as synonymous with ‘non-spatiotemporal’. These A-objects, as he calls them, fail to exemplify those properties at all but do, however, *encode* them. As he notes, the distinction between exemplifying and encoding properties is due to Ernst Mally. Abstract objects have content not by exemplifying properties but only by encoding them. Abstract objects that encode properties serve two purposes (p.15):

- They serve as intentional objects of states directed towards nonexistents.
- They also serve to characterize and reify the content of mental representations.

Zalta's reasoning for A-objects would seem to be:

- There must be some way or other in which the golden mountain *has* the properties of being golden and being a mountain.
- But, in the case of the golden mountain, ‘having those properties’ cannot be understood as ‘exemplifying those properties’.
- Therefore, there must be some way of having properties which neither is nor entails exemplifying them.
- Call this other way ‘encoding’. And call the object which encodes properties an *abstract* one. Let concrete objects be said to *exist*, and abstract objects be said not to exist, but merely to *be*.

Although it is clear what encoding is meant to achieve, it is not quite so clear what it actually is - no more clear, it would seem, than the mediaeval notion of intentional existence, nor any more clear than Parsons' nuclear/extranuclear distinction.

Why draw the ‘exists’/‘is’ distinction? Because it seems intuitively clear that ‘Pegasus’, ‘Zeus’, and ‘Hamlet’ are names of nonexistent, mythical, and fictional creatures. After all, ‘the logic of natural language seems to presuppose that it makes sense to refer to and talk about these creatures’ (p.103) Indeed, if ‘Quine were right when he says that "Hamlet doesn't exist" means "$\sim(\exists x)(x = h)$", then

"Hamlet" would fail to denote', and that would make quite mysterious the natural inference from 'John's paper is about Hamlet' to 'John's paper is about something' (p.104) Consequently, there is indeed a case for not dismissing Pegasus and others as complete nonentities, but for admitting that they do have some kind of entity. One might even be tempted to say that they exist, except that this could be taken to imply that they were no less real than Aristotle, Plato and Julius Caesar, which few would be prepared to accept. To do justice to these considerations, therefore, we are urged to allow that Pegasus and Zeus truly *are* (or have being), but not to go so far as to accept that they *exist* (or have existence). For Zalta, 'is' or 'being' is represented by '∃' and is called 'logical or metaphysical existence', while existing is called 'physical existence' and 'exists' is represented by 'E!'. It is with the aid of this distinction between existing and being that Zalta develops an intensional logic which handles intentional objects with a facility not to be found in non-intensional logics.

The relative positions of Parsons and Zalta on 'exists' and 'is' can be summarized as follows:

1. *Parsons*: Distinguishes 'exists' from 'is', existence from being. Both 'exists' and 'is' are first-level predicates, since each is said of *concrete* objects, the former of complete objects and the latter of incomplete. Indeed, Parsons explicitly denies that 'is' should be rendered as '∃'. (p.6)
2. *Zalta*: Likewise distinguishes 'exists' from 'is', existence from being. 'Exists' ('E!') is a first-level predicate. However, 'is' is predicated of abstract entities and, contrary to Parsons, is represented by '∃', which would indicate that it is a second-level predicate.

We have been attending to 'exists' and 'is' not for their own sake but purely as a prolegomenon to an ontological question, namely, that of existence. It is not for the present entry to discuss the relative merits of Frege-Russell logic (perhaps augmented by treatments of intentional propositions suggested by the likes of Howell and van Inwagen) vs intensional logics, nor the merits of Parsons' intensional proposals vs those of Zalta. The relevance of all those logics to our present purposes lies solely in their implications for the ontological status of existence, namely, that it is a first-level property. Whether it is real or Cambridge, however, will not be settled by logic but only by extra-logical considerations.

Criticisms of First-Level Use of 'Exists'

Critical responses to the suggestion that 'exists' is predicable of individuals are broadly of two kinds. One it to argue against it, the other to accept it but to restrict its consequences. Both have now to be outlined.

Argument against First-Level Use of 'Exists': C.J.F.Williams has challenged advocates of an actuality sense of 'exists' to give a genuine non-philosophical example in which 'exists' is predicated of an individual. 'Socrates no longer exists' and 'Socrates might never have existed' have been suggested, because it would seem that the former can be understood as 'It used to be the case that (Socrates exists), but it is not now the case that (Socrates exists)', and the latter as 'It might have been the case but was never the case that (Socrates exists)'. Thus understood, each proposition has 'Socrates exists' embedded in it, and hence could not make sense unless the embedded proposition also made sense, which it could

not do unless ‘exists’ were predicable of Socrates.

These putative counter-examples have failed to impress Williams (*Being, Identity, and Truth*, pp.28-33), who rejects them on two grounds:

1. Despite appearances to the contrary, ‘Socrates exists’ is *not* embedded in either proposition. Hence, they are not examples of ‘exists’ being predicated of an individual.
2. Despite its apparent absence, it is the there-is sense of ‘exists’ (and not any actuality sense) that is implicit in both propositions.

Williams agrees that a first-level use of ‘exists’ would require ‘Socrates no longer exists’ to be rendered as ‘It used to be the case that (Socrates exists), but is not now the case that (Socrates exists)’. However, because he denies any distinction between external and internal negation, he is able to say that the second clause - ‘it is not now the case that (Socrates exists)’ - should be understood as ‘Socrates does not exist’. ‘Socrates does not exist’ could never be true, however, since there could never be any fact about Socrates without Socrates himself being a constituent of it. Because a nonexistent Socrates cannot be a constituent of anything, ‘Socrates does not exist’ can make no sense. Moreover, no propositions of which it were a logical part could make any sense either. Hence, if it were a logical part of ‘Socrates no longer exists’, that proposition would make no sense. But, since it undoubtedly does make sense, neither ‘Socrates exists’ nor ‘Socrates does not exist’ can be embedded in it - contrary to what supporters of a first-level use of ‘exists’ affirm.

Having argued against any first-level use of ‘exists’ in ‘Socrates no longer exists’, Williams has to explain how that proposition is to be understood if it neither expresses any fact of which Socrates would be a constituent, nor is it *about Socrates*. He does so by reminding us that ‘when we are attempting to discover whether something is the same as something which possessed some property at an earlier time, we need predicables of reidentification’. As he explains, this means that we need two predicables, one being true of Socrates before he died and the other true of him after his death. With this in mind, he claims that ‘Socrates no longer exists’ is to be understood simply as the denial that there is any such pair of predicables. It has therefore to be understood as ‘There is *no* pair of predicables of reidentification such that one of them can be truly predicated of Socrates and the other truly predicated of someone at the present moment’.

The virtue of this interpretation, says Williams, is that it says something without, however, implying either that there is nothing for it to be about or that there is a fact of which Socrates would have to be a constituent. Although ‘Socrates no longer exists’ would be senseless if ‘exists’ were to be used in the actuality sense, it would make perfectly good sense if the there-is sense were employed.

Williams' strategy with ‘Socrates might not have existed ‘is much the same as with ‘Socrates no longer exists’. To begin with, he rejects understanding it as ‘It might have been the case that it was *not* always the case that (Socrates exists)’. Rather, the ‘not’ has to occur within the brackets, as in ‘It might have been the case that it was always the case that (Socrates does *not* exist)’. As in the earlier case, this relies

on denying any distinction between internal and external negation. Once the proposition is understood in this way, it is then open to criticism for attempting at one and the same time both to say something about a person and to imply that there is no such person to say anything about. In other words, it is an attempt to present a fact about Socrates without his being a constituent of that fact.

The problem is to find an interpretation of ‘Socrates might never have existed’ in which ‘exists’ would not even seem to be predicated of Socrates. Williams' candidate is, ‘There is a property which was an essential property of Socrates, and it might have been the case that nothing at all ever possessed this property.’ This does not imply that there is any fact having a nonexistent Socrates as one of its constituents. Consequently, propositions like ‘Socrates might never have existed’ do have a place in the language, but only if that they are understood as being about one of Socrates' properties rather than about Socrates himself.

If Williams is right, the two propositions which certainly do appear to be saying something about Socrates, are in fact saying nothing at all about him. Rather, they are merely saying something about the *instantiation of properties*. ‘Socrates might never have existed’ is saying that *there is* an essential property which belonged to Socrates and which might have belonged to no one. ‘Socrates no longer exists’ is saying that *there is* no pair of properties of reidentification one of which belongs to someone now, the other of which belonged to Socrates.

Advocates of the two-sense thesis would not feel threatened by these considerations. Rather, they would argue that it is important to realize that the arguments against ‘Socrates exists’ being embedded in the two propositions were based on the assumption that no property *at all* could be acquired by any individual who no longer existed. This assumption, however, is merely a half-truth. What is true is that no *real* property can be acquired by such an individual: Socrates cannot become wise, or tired, or angry, and so on after his death. He can have no more real properties after death than he had during his lifetime. About Cambridge properties, however, that is far from true, for he can become admired by antipoedeans, emulated by twentieth century students, reviled by twenthieth century totalitarian regimes, and so on and so on: the list could go on forever.

The question to be asked, therefore, about the predicate ‘does not exist’ is not simply whether it would, if admitted as a first-level predicate, attribute some property to a nonexistent individual, but whether that property would be a *real* one. One has only to ask what the putative property would be, in order to be assured that the answer is ‘no’; for the property in question would be non-existence, and non-existence would surely have to be the very paradigm of a Cambridge property. But, once that is accepted, there would be no reason to doubt that ‘Socrates exists’ is indeed embedded in both ‘Socrates no longer exists’ and in ‘Socrates might never have existed’.

What weight, then, should be attached to Williams' rendering of the two propositions in terms of the there-is sense of ‘exists’ rather than of the actuality sense? According to some critics, not much. The only thing to commend those renderings was the conviction that they would make no sense if understood to be employing the actuality sense. If, as the critics argue, that conviction is ill-founded, Williams' strained interpretations would have little to recommend them.

Two further objections to the first-level use of ‘exists’ are raised by Michael Dummett. One of them makes the valid point that it would follow from the two-sense thesis that the first- and second-level senses of ‘exists’ would be equivocal. Why? Because, as Dummett says, there could be no greater difference of sense than ‘one involving a difference of logical type, that between a quantifier and a first-level predicate’.(*Frege, Philosophy of Language*, p.386) The defender of the two-sense thesis would certainly agree that a difference of logical type is an absolute one, but would need to be convinced that this precludes there being any connection whatever between the two senses. As a counter-example to Dummett's claim, Geach has drawn our attention to two uses of ‘disappears’. The sense in ‘When the rescuers reached the site of the accident, the body had disappeared’ differs from that in ‘Dinosaurs have disappeared from the face of the earth’. Even though the former ia first-level use of ‘disappears’ and the latter a second-level one, however, there is at least some connection between their senses, albeit not one of even partial univocity. In Geach's view, there is no reason why the two senses of ‘exists’ should not be similarly related.

Dummett's second objection concerns the first-level use of ‘exists’ in propositions like ‘Cleopatra no longer exists’, about which he maintains that, if ‘exists’ were being said of Cleopatra, it would mean that she no longer had a certain property. But this is unacceptable for ‘existence, even when temporal, is not a property that may be first acquired and later lost’, and it makes no sense to say or imply that it is.(*Op.cit.*, p.387) Defenders of the two-sense thesis would agree. Indeed, that is precisely why they insist that propositions like ‘Cleopatra no longer exists’, ‘Cleopatra came to exist’, and ‘Cleopatra ceased to exist’ are to be understood in such a way as certainly not to imply any acquisition or loss of existence. Rather, they are to be understood respectively as ‘It is no longer the case that (Socrates exists)’, ‘It came to be that (Socrates exists)’, and ‘It ceased to be that (Socrates exists)’, none of which carries the unacceptable implication that Socrates acquired or lost any property.

Attempts to Restrict the Consequences of ‘Exists’ being a First-Level Predicate: While not wanting to deny that ‘exists’ could be predicated of individuals, some would be much concerned with what might be inferred from such a doctrine. In particular, they would want to preclude any possibility of inferring that the property referred to by ‘exists’ (existence) might not only be a real property, but also one that was irreducible to any *non*-existential properties. That possibility would be removed if, as has been argued, ‘exists’ were merely a formal predicate, an excluder, a predicate variable, or one that did duty for a disjunction of predicates. As we shall see, no one of these proposals has gone unchallenged.

‘Exists’ a Formal Predicate?: It is worth considering whether existence might not be what Wittgenstein called a formal concept, and whether ‘exists’ might not be the kind of predicate that expresses such a concept, even if only improperly. Examples of such predicates occur in ‘2 is a number’, ‘"2" is a numeral’, ‘Tom is an object’, ‘"Tom" is a name‘, ‘"The mother of Socrates" is a complex.’ Although all the predicates are first-level ones, they attribute no real property to what they are said of, but simply place them in some category. The propositions in which they occur are all quite uninformative; and, although like tautologies in that particular respect, they are unlike tautologies in that their denial is not self-contradictory. ‘Black stones are not black’ is self-contradictory, whereas ‘2 is not a number’ is not, even though it can never be true. In these respects they have much in common with ‘exists’. Hence, it might be

suggested that ‘exists’, too, is simply a formal predicate, for it is commonly claimed that ‘Socrates exists’ is uninformative and that ‘Socrates does not exist’ is not self-contradictory, notwithstanding that in certain circumstances it would be extremely odd to affirm it.

Now, an interesting feature of the propositions listed above is that, despite not being tautologies, each of them is necessarily true. 2 cannot cease to be a number, ‘2’ cannot cease to be a numeral, Tom cannot cease to be an object, nor can ‘Tom’ cease to be a proper name. It may not have been necessary that there be a 2, ‘2’, Tom, or ‘Tom’; but, given that we do have them, it can never be false to predicate the relevant formal predicates of them. It is no more true to say ‘Socrates is no longer an individual’ than to say ‘2 is no longer a number’. Some would say that it is just that characteristic of formal predicates which disqualifies ‘exists’ from being one of them. If ‘exists’ were a formal predicate, then, once ‘Socrates exists’ were true, it could never be false. Yet, although ‘Socrates exists’ was once true, it not only can be false but indeed is now false. Consequently, ‘exists’ seems not to be a formal predicate, attractive as it may have been to think otherwise.

‘Exists’ an Excluder?: To have ruled out ‘exists’ from being a formal predicate is not necessarily to have ruled out all possibility of its being a first-level predicate without existence being a real property. One other possibility is that it be what Roland Hall has called ‘an excluder’, and which he introduces as follows:

> Adjectives that (1) are attributive as opposed to predicative, (2) serve to rule out something without themselves adding anything, and (3) ambiguously rule out different things according to context, I call "excluders".

As examples, he suggests ‘ordinary’, ‘absolute’, ‘accidental’, ‘barbarian’, ‘base’, ‘civil’, ‘real’, amongst many others. The one most relevant to present purposes, however, is ‘real’.

In Hall's view, ‘real’ is the kind of adjective that merely rules out something without itself adding anything. According to context, it can rule out *a*'s being imaginary, or artificial, or counterfeit. In doing so, however, it attributes nothing positive to what it is said of: its contribution is purely negative. Moreover, what it excludes varies with context, and therein, says Hall, lies its ambiguity. Although Hall himself does not suggest that ‘exists’ is an excluder, others have done so, and still others have suggested that ‘exists’ means simply ‘is real’. On either suggestion existence would not be a real property, and that is why these views might commend themselves to anyone who was bothered by the possibility of existence being a real property of things.

The question is whether ‘exists’ really does have the three marks required of an excluder. Since it is not an adjective at all, it obviously cannot be an attributive one. However, that is of no account, for in his closing remarks Hall allows that excluders may be found not only among adjectives, but also among ‘nouns and other parts of speech.’ The questions we have to ask of ‘exists’ therefore are:

- Is it ambiguous?

- Not merely can it be defined negatively, but must it be so defined?

If ‘exists’ is to be an excluder, the answer has to be ‘yes’ not merely to one of these questions, but to both. If we accept that ‘exists’ is ambiguous, then the question of its being an excluder will turn on whether it satisfies (2), e.g., on whether ‘*a* exists’ must be understood simply in terms of what *a* was precluded from being. If so, then no matter how different the context, ‘*a* exists’ could only be understood negatively, e.g., as ‘*a* is not-fictional’, ‘*a* is not-dead’, ‘*a* is not illusory’, ‘*a* is not-mythical’, or ‘*a* is not-nonexistent’. The simplest case to consider is the last. We might envisage a seer predicting that in two years a son would be born to parents *b* and *c*, and that he would be called ‘Socrates’. When the prediction was fulfilled, we might imagine the seer announcing triumphantly ‘At last Socrates exists, just as I said he would.’ If ‘exists’ were an excluder, then the only way of understanding the seer would be as excluding some property from Socrates; and in this case the property excluded would be that of non-existence. As said by the seer, therefore, ‘At last Socrates exists’ could only mean ‘At last Socrates is not-nonexistent’. If he really were to mean that, he would have to explain just when Socrates could ever have been said to be nonexistent, i.e., never to have existed. In fact, Prior, Ryle, and others have maintained that before Socrates existed he could not even have been referred to, and hence at that time nothing at all could have been attributed to him, not even the property of being nonexistent. In that case, it would be impossible for ‘At last Socrates exists’ to mean ‘At last Socrates is no longer nonexistent’. If this is correct, ‘exists’ could not be an excluder, for there was never any property for it to exclude.

Still, in other contexts ‘Socrates exists’ might be proposed as meaning ‘Socrates is not-dead’ or ‘Socrates is non-fictional’, and ‘exists’ as excluding from Socrates the properties of being dead and being fictional respectively. The first case can scarcely be evidence for ‘exists’ being an excluder, for ‘is dead’ is itself to be understood as ‘is not-alive’. If it were evidence for anything, it would be for ‘exists’ as a synonym for ‘is alive’, except that ‘The Euston Arch no longer exists’ could hardly be understood as ‘The Euston Arch is no longer alive’.

As for ‘Socrates is non-fictional’ (‘Socrates is a non-fictional character’ would be better), it could support the claim that ‘exists’ is an excluder only if Socrates really could have been a fictional character. That, however, could have occurred only if a fictional character could ever be the same person as a real-life one, something which is extremely debatable to say the least, even though it is entirely possible that a real-life character should satisfy the same *description* as a fictional one. Precisely the same point can be made about any attempt to depict ‘exists’ as excluding ‘is mythical’. Since Socrates never could have been either a fictional or mythical character, there is nothing for ‘exists’ to exclude. That is not to say that there is anything wrong with saying ‘Socrates is not fictional’ or ‘Socrates is not mythical’, but only that it is misleading to construe those propositions as ‘Socrates is not-fictional’ and ‘Socrates is not-mythical’ rather than as ‘Not(Socrates is fictional)’ and ‘Not(Socrates is mythical)’. From all this it is clear enough that the answer to (ii) above is ‘No, "exists" need not be defined or understood purely negatively.’ Once again, it would seem that ‘exists’ cannot be an excluder.

‘Exists’ a Predicate Variable or a Disjunction of Predicates?: It has been suggested that ‘exists’ should be construed as a predicate variable or as a disjunction of predicates. In the former case ‘a exists’ would be rendered as ‘a has some property or other’ or ‘(∃*P*)(*P* is had by *a*)’, where *‘P’* is a predicate variable.

In the latter case '*a* exists' might be rendered as '*a* is *F* or *G* or *H*', where *'F'*, *'G'* and *'H'* are first-level predicates. In either case the result would be to disqualify existence from being an irreducible property of *a*. In the first case, although *a* might be allowed to have the properties referred to by whatever predicates are substituted for *'P'*, it would have no irreducibly existential property. Similarly in the second case; although *a* might have one of the properties *F*, *G*, and *H*, it would have no irreducible property of existence.

If the first suggestion were correct, 'Socrates does not exist' could be rendered as 'Socrates has no properties'. Likewise, if the second suggestion were correct, 'Socrates does not exist' could be rendered as 'Socrates has neither *F*, nor *G*, nor *H*', i.e., 'Socrates has no properties'. In either case, therefore, 'Socrates does not exist' could be understood as 'Socrates has no properties'. Defenders of the actuality sense of 'exists' would point out, however, that 'Socrates has no properties' could be true only if Socrates were a bare particular. On the contrary, 'Socrates does not exist' could be true irrespective of whether Socrates was or was not a bare particular. Yet, there should be no such difference, if 'Socrates does not exist' were to be understood as 'Socrates has no properties'. Thus, they argue that 'Socrates exists' can be rendered neither by 'Socrates has some property or other' nor by 'Socrates is either *F* or *G* or *H*'.

Ontological Implications of the Debate

Ontological Implications of 'Exists' being a Second-Level Predicate: Since, on this view, 'exists' is solely a second-level predicate, existence would ipso facto be a second-level property, a property of first-level properties. What it tells us about them is simply how often they are instantiated, namely, at least once. Moreover, since it is not a property of individuals, a fortiori it is incapable of adding anything to them, thus confirming the views of Hume, Kant, and many others.

If, as Russell, Quine, and Williams maintain, 'Socrates exists' is not about Socrates but is about various properties, this suggests the possibility that even *non*-existential propositions like 'Socrates is wise' could likewise be merely about properties rather than about Socrates. The result would be an ontology in which properties were ontologically primitive, with individuals being reducible to them. Russell and Goodman certainly accepted that view in their notion of individuals as mere 'bundles' of properties. There have indeed been a variety of bundle theories, differing according as the bundles' constituents and/or structures were different. For Russell and Goodman the constituents were universal properties, for Castaneda they were guises (constructed inter alia from properties), and for D.C.Williams and K.Campbell the constituents were not universal properties but *singular* ones known as 'tropes'. Closely related to these theories is one kind of haecceity theory, according to which individuals would be constructs of universal properties with the very important addition of one singular property (an haecceity). All such theories stand on its head the Aristotelian ontology, in which both individuals and properties are primitive. Properties, however, are ontologically posterior to individuals, for there can be no universals existing outside individuals, and their instances are individuated by the individual in which they are instantiated.

However, although the reducibility of individuals to various complexes of properties would entail a second-level view of existence, the converse is not true: the second-level view of 'exists' and existence

does not entail the reducibility of individuals, but is merely consistent with it and therefore congenial to those who have independent reasons for espousing it. Even though Williams, for example, holds to a second-level view of ‘exists’ in his interpretation of ‘Socrates no longer exists’, he could quite consistently hold to a first-level view of ‘is walking’ in his interpretation of ‘Socrates is no longer walking’.

Ontological Implications of ‘Exists’ being a First-Level Predicate:For the two-sense theorist, as well as for Parsons and Zalta, existence is a first-level property and, since ‘exists’ is arguably irreducible to other predicates, existence is arguably irreducible to other properties. The question, then, is whether it is a Cambridge property or a real one. An argument for its not being a Cambridge property is simply this:

- A Cambridge property is the referent either of a relational predicate or of a purely formal predicate.
- But, ‘exists’ is neither a relational nor a formal predicate. Not formal, for reasons given earlier. Not relational, because the totality of universes cannot be related to any other spatio-temporal entity, yet can quite properly be said to exist.
- Therefore, ‘exists’ is not a Cambridge property.
- But, if ‘exists’ is a property but not a Cambridge one, it is a real one.

A prime stumbling block to this conclusion is the objection raised by Hume, Kant, and many others that Socrates' existence could be a real property only if it added something to him, which it clearly does not. The obvious assumption here is that, if his existence were a real property, it would have to be like his other real properties such as his wisdom; and since they do add something to him, his existence should either do the same or forfeit all claim to being a real property. Underlying this suggestion is the further assumption that the relation between Socrates and his existence must duplicate that between him and his wisdom not merely in some respects but in all respects.

Now, a condition of wisdom and existence being properties of Socrates is that they each be individuated by him. That is to say, just as the wisdom-of Socrates must differ at least numerically from the wisdom-of-Plato, so too must the existence-of-Socrates differ at least numerically from the existence-of-Plato. (Although bundle theorists of all persuasions would deny this inference, their denials can be discounted, since it can be argued that each version of the theory entails the self-defeating conclusion that in some cases even individuals could themselves be instantiated in other individuals.) It is one thing, however, to claim (correctly) that existence and wisdom have both to be individuated by Socrates, but quite another to say that both individuations must have the same ground. In the case of his wisdom and many other properties, he individuates them in being their recipient. Yet, although he clearly could not be the recipient of his existence, that need not preclude there being some other way in which he does individuate it. If there were, his existence would be no less entitled to be called a property than is his wisdom.

Is there such a way? It has been argued that there is, for Socrates would individuate his existence if he were not its recipient but its *bound*. (Cf. B.Miller, *The Fullness of Being*, chapter 4) The notion of a bound is more than a merely a spatial one, for there are also bounds of thought, bounds of desire, artistic bounds, and so on. Socrates would be the bound of his existence in respect of all human areas. In being

bounded by him, his existence would be individuated and distinguished from Plato's no less than, in being *received* by Socrates, his wisdom is individuated and distinguished from Plato's. Moreover, since no bound can be real unless what it bounds is also real, the fact that Socrates is real would entail that what he bounds (his existence) must be real as well. The salient point, however, is that it makes no sense to speak of a thing that is bounded being added to by its bound. Thus, even though it makes no sense to say that Socrates' existence adds anything to him, that would not detract from its being not only a property, but a real one to boot.

From this conclusion follow two interesting consequences, one ontological and the other logical. The former is that it would remove the misconception of existence as the most impoverished of properties. This view derives from an understanding of existence as simply ‘that attribute which is common to mice and men, dust and angels’. (A.Kenny, *The Five Ways*, London, Routledge and Kegan Paul, 1969, p.92) If, however, instances of existence were both real and bounded by the individuals that had them, then not only would Kenny's inference be invalid, but his conclusion would be false. This is because the wealth or poverty of instances of existence would vary in direct relation to the constricting character of their bounds. An amoeba would be a more constricting bound than a gazelle, which in turn would be more constricting than a human. And, naturally, there would be variations from one amoeba to another, from one gazelle to another, and from one human to another. Thus, the richness or poverty of existence would be far from invariant across the whole range of individuals, as Kenny and others have supposed it to be.

This ontological point has a logical corollary. It has commonly been thought that a first-level role for ‘exists’ in ‘Socrates exists’ would be the same as the innumerable predicates like ‘is brown’ in ‘Socrates is brown’ and ‘This gazelle is brown’. The point about ‘is brown’ is that it can attribute exactly the same kind of property to individuals as diverse as Socrates, a gazelle, and even a plank of wood: it is possible that the brownness of each individual differ neither in kind nor degree from that had by any other. To think of ‘exists’ in this way would be to regard it as attributing to Socrates neither more nor less that it does to a grain of sand.

What the analogy ignores, however, is that not all predicates conform to the model of ‘is brown’. An everyday example of a quite different model is ‘is fast’ in ‘Simon (a snail) is fast’, ‘Socrates is fast’, ‘Gerry (a gazelle) is fast’ and ‘Fred (a fighter plane) is fast’. The relevance of these four propositions is that sameness of predicate in each of them does not entail sameness of speed in each of their subjects. On the contrary, the property of being fast is directly relative to whatever its subject may be. Similarly with ‘is big’, which can be said of a flea no less than of an elephant or a skyscraper without however attributing the same size to each. ‘Fast’ and ‘big’ are what Geach has called attributive adjectives; ‘brown’ is called a predicative adjective. If instances of existence vary in direct relation to the individuals that bound them, it is clear that ‘exists’ cannot be like ‘is brown’, but is in fact like ‘is fast’ and ‘is big’, for which reason we might call it not an attributive adjective (for it is not an adjective at all), but an attributive term.

Of course, if existence proved not to be a real property, then neither the ontological nor the logical point would ensue.

Saint Thomas Aquinas

Thomas Aquinas (1225-1274) lived at a critical juncture of western culture when the arrival of the Aristotelian *corpus* in Latin translation reopened the question of the relation between faith and reason, calling into question the *modus vivendi* that had obtained for centuries. This crisis flared up just as universities were being founded. Thomas, after early studies at Montecassino, moved on to the University of Naples, where he met members of the new Dominican Order. It was at Naples too that Thomas had his first extended contact with the new learning. When he joined the Dominican Order he went north to study with Albertus Magnus, author of a paraphrase of the Aristotelian *corpus*. Thomas completed his studies at the University of Paris, which had been formed out of the monastic schools on the Left Bank and the cathedral school at Notre Dame. In two stints as a regent master Thomas defended the mendicant orders and, of greater historical importance, countered both the Averroistic interpretations of Aristotle and the Franciscan tendency to reject Greek philosophy. The result was a new *modus vivendi* between faith and philosophy which survived until the rise of the new physics. Thomas's theological writings became regulative of the Catholic Church and his close textual commentaries on Aristotle represent a cultural resource which is now receiving increased recognition. The following account concentrates on Thomas the philosopher and presents him as fundamentally an Aristotelian.

Life and Works

Vita Brevis

Thomas was born in 1225 at Roccasecca, a hilltop castle from which the great Benedictine abbey of Montecassino is not quite visible, midway between Rome and Naples. At the age of five, he was entered at Montecassino where his studies began. When the monastery became a battle site -- not for the last time -- Thomas was transferred by his family to the University of Naples. It was here that he came into contact with the "new" Aristotle and with the Order of Preachers or Dominicans, a recently founded mendicant order. He became a Dominican over the protests of his family and eventually went north to study, perhaps first briefly at Paris, then at Cologne with Albert the Great, whose interest in Aristotle strengthened Thomas's own predilections. Returned to Paris, he completed his studies, became a Master and for three years occupied one of the Dominican chairs in the Faculty of Theology. The next ten years were spent in various places in Italy, with the mobile papal court, at various Dominican houses, eventually in Rome. From there he was called back to Paris to confront the hullabaloo variously called Latin Averroism and Heterodox Aristotelianism. After this second three year stint, he was assigned to Naples. In 1274, on his way to the Council of Lyon, he fell ill and died on March 7 in the Cistercian abbey at Fossanova, which is perhaps twenty kilometers from Roccasecca.

Education

Little is known of Thomas's studies at Montecassino, but much is known of the shape that the monastic schools had taken. They were one of the principal conduits of the liberal arts tradition which stretches back to Cassiodorus Senator in the 6^{th} century. The arts of the trivium (grammar, rhetoric, logic) and those of the quadrivium (arithmetic, geometry, music and astronomy) were fragments shored against the ruinous loss of classical knowledge. They constituted the secular education that complemented sacred doctrine as learned from the Bible. When Thomas transferred to Naples, his education in the arts continued. Here it would have been borne upon him that the liberal arts were no longer adequate categories of secular learning: the new translations of Aristotle spelled the end of the liberal arts tradition, although the universities effected a transition rather than a breach.

Taking Thomas's alma mater Paris as reference point, the Faculty of Arts provided the point of entry to teen-aged boys. With the attainment of the Master of Arts at about the age of 20, one could go on to study in a higher faculty, law, medicine or theology. The theological program Thomas entered in Paris was a grueling one, with the master's typically attained in the early thirties. Extensive and progressively more intensive study of the scriptures, Old and New Testament, and of the summary of Christian doctrine called the *Sentences* which was compiled by the twelfth century Bishop of Paris, Peter Lombard. These close textual studies were complemented by public disputations and the even more unruly quodlibetal questions. Modeled more or less on the guilds, the student served a long apprenticeship, established his competence in stages and eventually, after a public examination was named a master and then gave his inaugural lecture.

Writings

Thomas's writings by and large show their provenance in his teaching duties. His commentary on the *Sentences* put the seal on his student days and many of his very early commentaries on Scripture have come down to us. But from the very beginning Thomas produces writings which would not have emerged from the usual tasks of the theological master. *On Being and Essence* and *The Principles of Nature* date from his first stay at Paris, and unlike his commentaries on Boethius' *On the Trinity* and *De hebdomadibus*, are quite obviously philosophical works. Some of his disputed questions date from his first stint as regius master at Paris. When he returned to Italy his productivity increased. He finished the *Summa contra gentiles*, wrote various disputed questions and began the *Summa theologiae*. In 1268, at Rome, he began the work of commenting on Aristotle with *On the Soul*, and during the next five or six years commented on eleven more (not all of these are complete). During this time he was caught up in magisterial duties of unusual scope and was writing such polemical works as *On the Eternity of the World* and *On There Being Only One Intellect*.

At Naples, he was given the task of elevating the status of the Dominican House of Studies. His writing continued until he had a mystical experience which made him think of all he had done as "mere straw." At the time of his death in 1274 he was under a cloud in Paris and in 1277, 219 propositions were condemned by a commission appointed by the Bishop of Paris, among them tenets of Thomas. This was soon lifted, he was canonized and eventually was given the title of Common Doctor of the Church. But the subtle and delicate assimilation of Aristotle that characterized his work in both philosophy and theology did not survive his death, outside the Dominican Order, and has experienced ups and downs ever since.

Philosophy and Theology

Many contemporary philosophers are unsure how to read Thomas. As the above sketch makes clear, he was a professional theologian. Nonetheless, we find among his writings works anyone would recognize as philosophical and the dozen commentaries on Aristotle increasingly enjoy the respect and interest of Aristotelian scholars. But his best known work is the *Summa theologiae*, which is most often cited when Thomas's position on this or that is sought. How can a theological work provide grist for philosophical mills? How did Thomas distinguish between philosophy and theology?

Sometimes, Thomas puts the difference this way: "... the believer and the philosopher consider creatures differently. The philosopher considers what belongs to their proper natures, while the believer considers only what is true of creatures insofar as they are related to God, for example, that they are created by God and are subject to him, and the like." (*Summa contra gentiles*, bk II, chap. 4) Since the philosopher too, according to Thomas, considers things as they relate to God, this statement does not put the difference in a formal light.

The first and major formal difference between philosophy and theology is found in their principles, that

is, starting points. The assumptions of the philosopher, that to which his discussions and arguments are ultimately driven back, are in the public domain. They are things that everyone knows; they are where disagreement between us must come to an end. These principles are not themselves the products of proof -- which does not of course mean that they are immune to rational analysis and inquiry -- and thus they are said to be known by themselves (*per se*, as opposed to *per alia*). This is proportionately true of each of the sciences, where the most common principles just alluded to are in the background and the proper principles or starting points of the particular science function regionally as the common principles do across the whole terrain of thought and being.

By contrast, the discourse of the theologian is ultimately driven back to starting points or principles that are held to be true on the basis of faith, that is, the truths that are authoritatively conveyed by the Bible. Some believers reflect on these truths and see other truths implied by them, spell out their interrelations and defend them against the accusation of being nonsense. Theological discourse looks like any other discourse and is, needless to say, governed by the common principles of thought and being, but it is characterized formally by the fact that its arguments and analyses are truth-bearing only for one who accepts Scriptural revelation as true.

This provides a formal test for deciding whether a piece of discourse is philosophical or theological. If it relies only on truths anyone can be expected to know about the world, and if it offers to lead to new truths on the basis of such truths, and only on that basis, then it is philosophical discourse. On the other hand, discourse whose cogency -- not formal, but substantive -- depends upon our accepting as true such claims as that there are three persons in one divine nature, that our salvation was effected by the sacrifice of Jesus, that Jesus is one person but two natures, one human, one divine, and the like, is theological discourse. Any appeal to an authoritative scriptural source as the necessary nexus in an argument is thereby other than philosophical discourse.

More will be said of this contrast later, but this is the essential difference Thomas recognizes between philosophy and theology. I will conclude this paragraph with a passage in which Thomas summarizes his position. He is confronting an objection to there being any need for theological discourse. Whatever can be the object of inquiry will qualify as a being of one sort or another; but the philosophical disciplines seem to cover every kind of being, indeed there is even a part of it which Aristotle calls theology. So what need is there for discourse beyond philosophical discourse?

> ....it should be noted that different ways of knowing (*ratio cognoscibilis*) give us different sciences. The astronomer and the natural philosopher both conclude that the earth is round, but the astronomer does this through a mathematical middle that is abstracted from matter, whereas the natural philosopher considers a middle lodged in matter. Thus there is nothing to prevent another science from treating in the light of divine revelation what the philosophical disciplines treat as knowable in the light of human reason. (*Summa theologiae*, Ia, q. 1, a., ad 2)

Christian Philosophy

It will be observed that the formal distinction between philosophical and theological discourse leaves untouched what has often been the mark of one who is at once a believer and a philosopher. It is not simply that he might on one occasion produce an argument that is philosophical and at another time one that is theological; his religious beliefs are clearly not put in escrow but are very much in evidence when he functions as a philosopher. Many of the questions that can be raised philosophically are such that the believer already has answers to them -- from his religious faith. How then can he be thought to be ready to follow the argument whither it listeth, as the objector is unlikely to put it? Furthermore, the inquiries in which the believer who philosophizes engages will often betray his religious beliefs.

When such observations turn into objections, perhaps into the accusation that a believer cannot be a proper philosopher, there is often an unexamined notion of what a proper philosopher looks like. The proper philosopher may be thought to be someone -- perhaps merely some mind -- without antecedents or history who first comes to consciousness posing a philosophical question the answer to which is pursued without prejudice. But of course no human being and thus no philosopher is pure reason, mind alone, without previous history as he embarks on the task of philosophizing. One has necessarily knocked about in the world for a long time before he signs up for Philosophy 101. He has at hand or rattling around in his mind all kinds of ready responses to situations and questions. He very likely engaged in some kind of inquiry about whether or not to begin the formal study of philosophy in the first place. This may be acknowledged, but with the proviso that step one in the pursuit of philosophy is to rid the mind of all such antecedents. They must be put in the dock, put in brackets, placed in doubt, regarded with suspicion. Only after appropriate epistemological cleansing is the mind equipped to make its first warranted knowledge claim. Knowledge thus becomes a deliverance of philosophy, a product of philosophizing. Outside of philosophy there is no knowledge.

The preceding paragraph has been meant to capture the salient note of much modern philosophy since Descartes. Philosophy is first of all a search for defensible knowledge claims, and for the method according to which it will be found. As opposed to what?

As opposed to the view of philosophy described in paragraph 2, Thomas understands philosophizing to depend upon antecedent knowledge, to proceed from it, and to be unintelligible unless, in its sophisticated modes, it can be traced back to the common truths known to all. But this tracing back will pass through very different terrains, depending on the upbringing, culture and other vagaries and accidents of a given person's experience. The pre-philosophical -- I refer to the formal study of philosophy -- outlook of the believer will be characterizable in a given way, a way suggested above. It is more difficult to characterize the pre-philosophical attitudes and beliefs out of which the non-believer philosophizes. Let us imagine that he holds in a more or less unexamined way that all events, including thinking, are physical events. If he should, as a philosopher, take up the question of the immortality of the soul, he is going to regard with suspicion those classical proofs which rely on an analysis of thinking as a non-physical process. The Christian, on the other hand, will be well-disposed towards efforts to prove the immortality of the human soul and will accordingly approach descriptions of thinking as non-physical sympathetically. He is unlikely to view with equanimity any claim that for human beings death is the utter end.

The importance of this is that a believer runs the risk of accepting bad proofs of the immateriality of thinking and thus of the human soul. On the other hand, a committed materialist may be too quick to accept a bad proof that thinking is just a material process. Such antecedent stances are often the reason why philosophical agreement is so hard to reach. Does it make it impossible? Do such considerations destroy any hope of philosophical objectivity? Surely not, in principle. Believers and non-believers should be able to agree on what counts as a good proof in a given area even if they expect different results from such a proof. Thinking either is or is not merely a physical process and antecedent expectations do not settle the question, however they influence the pursuit of that objective resolution. But the important point is that antecedent dispositions and expectations are the common condition of philosophers, believers and unbelievers alike. Of course, believers hold that they have an advantage here, since the antecedents that influence them are revealed truths, not just hearsay, received opinion, the *zeitgeist* or prejudice.

Thomas and Aristotle

As a philosopher, Thomas is emphatically Aristotelian. His interest in and perceptive understanding of the Stagyrite is present from his earliest years and certainly did not await the period toward the end of his life when he wrote his close textual commentaries on Aristotle. When Thomas referred to Aristotle as the Philosopher, he was not merely adopting a *facon de parler* of the time. He adopted Aristotle's analysis of physical objects, his view of place, time and motion, his proof of the prime mover, his cosmology. He made his own Aristotle's account of sense perception and intellectual knowledge. His moral philosophy is closely based on what he learned from Aristotle and in his commentary on the *Metaphysics* he provides the most cogent and coherent account of what is going on in those difficult pages. But to acknowledge the primary role of Aristotle in Thomas's philosophy is not to deny other influences. Augustine is a massively important presence. Boethius, Pseudo-Dionysius and Proclus were conduits through which he learned Neo-platonism. There is nothing more obviously Aristotelian about Thomas than his assumption that there is something to be learned from any author, if only mistakes to be avoided. But he adopted many features from non-Aristotelian sources.

This has led some to suggest that what is called Thomistic philosophy is an eclectic hodgepodge, not a set of coherent disciplines. Others, struck by the prominence in Thomas of such Platonic notions as participation, have argued that his thought is fundamentally Platonic, not Aristotelian. There is also an undeniable anti-Aristotelian animus in some influential students of Thomas, for example, Etienne Gilson. For Gilson, there is a radically original Thomistic philosophy which cannot be characterized by anything it shares with earlier thinkers, particularly Aristotle.

The recognition that Thomas is fundamentally an Aristotelian is not equivalent to the claim that Aristotle is the only influence on him. It is the claim that whatever Thomas takes on from other sources is held to be compatible with what he already holds in common with Aristotle. And, of course, to draw attention to the sources of Thomas's philosophy is not to say that everything he holds philosophically can be parsed back into historical antecedents.

The Order of Philosophical Inquiry

Thomas takes "philosophy" to be an umbrella term which covers an ordered set of sciences. Philosophical thinking is characterized by its argumentative structure and a science is taken to be principally the discovery of the properties of kinds of things. But thinking is sometimes theoretical and sometimes practical. The practical use of the mind has as its object the guidance of some activity other than thinking -- choosing in the case of moral action, some product in the case of art. The theoretical use of the mind has truth as its object: it seeks not to change the world but to understand it. Like Aristotle, Thomas holds that there is a plurality of both theoretical and practical sciences. Ethics, economics and politics are the practical sciences, while physics, mathematics and metaphysics are the theoretical sciences.

That is one way to lay out the various philosophical disciplines. But there is another that has to do with the appropriate order in which they should be studied. That order of learning is as follows: logic, mathematics, natural philosophy, moral philosophy, metaphysics. The primacy of logic stems from the fact that we have to know what knowledge is so we will recognize that we have met its demands in a particular case. The study of mathematics comes early because little experience of the world is required to master it. But when we turn to knowledge of the physical world, there is an ever increasing dependence upon a wide and deep experience of things. Moral philosophy requires not only experience, but good upbringing and the banking of the passions. Metaphysics or wisdom, is the culminating and defining goal of philosophical inquiry: it is such knowledge as we can achieve of the divine, the first cause of all else.

Thomas commented on two logical works of Aristotle: *On Interpretation* (incomplete) and *Posterior Analytics*. On mathematics, there are only glancing allusions in Thomas's writings. Thomas describes logic as dealing with "second intentions," that is, with relations which attach to concepts expressive of the natures of existent things, first intentions. This means that logic rides piggy-back on direct knowledge of the world and thus incorporates the view that what is primary in our knowledge is the things of which we first form concepts. Mathematical entities are idealizations made by way of abstraction from our knowledge of sensible things. It is knowledge of sensible things which is primary and thus prior to the "order of learning" the philosophical sciences.

This epistemological primacy of knowledge of what we grasp by our senses is the basis for the primacy of the sensible in our language. Language is expressive of knowledge and thus what is first and most easily knowable by us will be what our language first expresses. That is the rule. It is interesting to see its application in the development of the philosophy of nature.

Composition of Physical Objects

The concern of natural science is of course natural things, physical objects, which may be described as "what come to be as the result of a change and undergo change." The first task of natural philosophy, accordingly, is to define and analyze physical objects.

The first thing to notice about this is the assumption that we begin our study of the natural world, not with the presumed ultimate alphabet with which macrocosmic things are spelled, but with a vague and comprehensive concept which encompasses whatever has come to be as the result of a change and undergoes change. The reader of Aquinas becomes familiar with this assumption. Thomas learned it from the beginning of Aristotle's *Physics*.

> The natural way of doing this is to start from the things which are more knowable and clear to us and to proceed towards those which are clearer and more knowable by nature; for the same things are not knowable relatively to us and knowable without qualification. So we must follow this method and advance from what is more obscure by nature, but clearer to us, towards what is more clear and more knowable by nature.
>
> Now what is to us plain and clear at first is rather confused masses, the elements and principles of which become known to us later by analysis. Thus we must advance from universals to particulars; for it is a whole that is more knowable to sense-perception, and a universal is a kind of whole, comprehending many things within it, like parts. Much the same thing happens in the relation of the name to the formula. A name, e.g. ‘Circle’, means vaguely a sort of whole: its definition analyses this into particulars. Similarly a child begins by calling all men father, and all women mother, but later on distinguishes each of them." (*Physics*, 1, 1.)

Thomas calls the movement from the more to the less general in a science the "order of determination" or specification of the subject matter. The first purchase on natural things is via "physical object" or "natural thing." The "order of demonstration" involves finding the properties of things as known through this general concept. Then, specifying the subject further, one seeks properties of things known through the less common concepts. For example, in plane geometry, one would begin with plane figure and discover what belongs to it as such. Then one would turn to, say, triangle and seek its properties, after which one would go on to scalene and isosceles. So one will, having determined what is true of things insofar as they are physical objects, go on to seek the properties of things which are physical objects of this kind or that, for example, living and non-living bodies.

Thomas emphasizes those passages in the Aristotelian natural writings which speak of the order of determination, that is, of what considerations come first and are presupposed to those that come later. In several places, Thomas takes great pains to array the Aristotelian natural writings according to this Aristotelian principle, most notably perhaps at the outset of his commentary on *Sense and sensibilia.* The *Physics* is the first step in the study of the natural world and exhibits the rule that what is first and most easily known by us are generalities. The language used to express knowledge of such generalities will have, as we shall emphasize, a long career in subsequent inquiries, both in natural philosophy and beyond. What is sometimes thought of as a technical vocabulary, perhaps even as Aristotelian jargon, is seen by Thomas Aquinas as exemplifying the rule that we name things as we know them and that we come to know more difficult things after the easier things and extend the language used to speak of the easier, adjusting it to an every expanding set of referents.

Matter and Form

Although natural things are first thought of and analyzed in the most general of terms, there are not of course any general physical objects, only particular ones. Thus, in seeking to discern what is true of anything that has come to be as a result of a change and is subject to change until it ceases to be, Aristotle had to begin with a particular example of change, one so obvious that we would not be distracted by any difficulties in accepting it as such. "A man becomes musical." Someone acquires a skill he did not previously have. Little Imogene learns to play the harmonica. Thomas pores over the analysis Aristotle provides of this instance of change and its product.

The change may be expressed in three ways:

1. Man becomes musical.
2. What is not-musical becomes musical.
3. A not-musical man becomes musical.

These are three different expressions of the same change and they all exhibit the form A becomes B. But change can also be expressed as From A, B comes to be. Could 1, 2 and 3 be restated in that second form? To say "From the not-musical the musical comes to be" and "From a not-musical man the musical comes to be" seem acceptable alternatives, but "From man musical comes to be" would give us pause. Why? Unlike "A becomes B" the form "From A, B comes to be" suggests that in order for B to emerge, A must cease to be. This grounds the distinction between the grammatical subject of the sentence expressing a change and the subject of the change. The definition of the subject of the change is "that to which the change is attributed and which survives the change." The grammatical subjects of 2 and 3 do not express the subject of the change, only in 1 is the grammatical subject expressive of the subject of the change.

This makes clear that the different expressions of the change involve two things other than the subject of the change: the characteristics of the subject before (not-musical) and after (musical) the change. These elements of the change get the names that stick from another example, whittling wood. The term for wood in Greek is *hyle* and the term for shape, the external contours of a thing, is *morphe*. In English, form, a synonym of shape, is used to express the characteristic that the subject acquires as the result of the change, e.g. musical. The characterization of the subject prior to the change as not having the form is called privation. Using this language as canonical, Aristotle speaks of the subject of the change as its *hyle* or matter, the character it gains as its *morphe* or form, and its prior lack of the form as its privation. Any change will involve these three elements: matter, form and privation. The product of a change involves two things: matter and form.

Change takes place in the categories of quality, quantity and place, but in all cases the terminology of matter, form and privation comes to be used. The terms bind together similar but different kinds of change -- a subject changing temperature is like a subject changing place or size.

Substantial Change

The analysis of change and the product of change begins with surface changes. Some enduring thing changes place or quality or quantity. But enduring things like men and trees and horses and the like have also come into being and are destined some day to cease to be. Such things are called substances. It is a given that there are substances and that they come to be and pass away. The question is: Can the analysis of surface change be adjusted and applied to substantial change? What would its subject be? Aristotle said that the subject of substantial change is known on an analogy with the subject of incidental or surface change. That is, if substances come to be as the result of a change, and if our analysis of change can apply, there must be a subject of the change. The subject of a surface or incidental change is a substance. The subject of a substantial change cannot be a substance; if it were, the result would be a modification of that substance, that is, an incidental change. But we are trying to understand how a substance itself comes into being as the result of a change. There must be a matter or subject but it cannot be matter in the sense of a substance. In order to signal this, we can call the matter *prime matter*, first matter. The form such a subject takes on as the result of the change cannot be an incidental form like size or location or temperature. Substances do not become or cease to be substances as a result of changes in these features. As the analysis of incidental change makes clear, the substance previously existed without the form it acquires in the change and it could lose it and still be itself. The form in a substantial change must be that which makes the substance to be what it is. Call it *substantial form*.

The thing to notice about this analysis is that substantial change is spoken of on an analogy with incidental change. The analysis of incidental change is presupposed and regulative. Moreover, the language used to speak of the elements of incidental change are extended to substantial change and altered in meaning so as to avoid equivocation. Thomas sees Aristotle's philosophical vocabulary arising out of analysis of what is most obvious to us and then progressively extended to more and more things insofar as the later is made known by appeal to the prior. Thus we can see that matter and form apply in a graded and connected way to the various kinds of incidental change and then to substantial change. It is this feature of Aristotle's language that Thomas adopts as his own. It both provides the lens through which Aristotle can be correctly seen and it provides a rule for knowing and naming that will characterize Thomas's use of Latin in philosophy and in theology as well.

Perception and Thought

When the discussion moves on from what may be said of all physical objects as such to an inquiry into living physical things, the analyses build upon those already completed. Thus, "soul" will be defined as the substantial form of living bodies. The peculiar activities of living things will be grouped under headings like nutrition and growth, sense perception and knowing and willing. Since a living thing sometimes manifests an instance of such activities and sometimes does not, they relate to it in the manner of the incidental forms of any physical object. And this provides Thomas, as he feels it had Aristotle, with a path of procedure. Let us skip to the cognitive activities of living things.

How can we best analyze perception -- that is, seeing, feeling, hearing, and the like? In continuity with what has gone before, the questions are put in this form: How best to analyze coming to see, coming to

feel, coming to hear, and the like. Seeing these on the analogy of change as already analyzed, we look for a subject, a privation and a form. The sensing subject is, say, the animal, but the proximate subjects to which they are attributed are the powers of sight, touch, hearing, and the like. An instance of seeing is describable as the power's moving from not seeing to seeing. Since the object of seeing is color, the change from not seeing to seeing issues in the power having the form of color.

We could give as an example of physical change, a substance acquiring a color. Now, while there are physical changes involved in sensation -- the organs are altered in the way physical bodies are -- that is not the change involved in perception as such. That is, in feeling a body my hand's own temperature is altered by the contact. But feeling cannot be just that, since any two physical bodies that come into contact would undergo a similar alteration of temperature. Feeling the temperature, becoming aware of it, is another sort of change, however much it depends on a contemporary physical change in the organs of sense. Having the color or temperature in this further sense is thus made known and named by reference to physical change. The fundamental difference between the two ways of acquiring a form is this. In a physical change of color, the change produces a new numerical instance of the color. In grasping or sensing a color, a numerically new instance of color does not result.

We have here the basis for talk of immateriality in perception. If the acquiring of a form by matter in physical change results in a new instance of the form and this is not the case with perception, we can make this point that acquiring the form in sensation is not identical to the acquiring of the form by matter *in the primary sense.* Thus, we both want to speak of the subject of sensation on an analogy with physical change *and* to distinguish the former from the latter. This is done by speaking of the immaterial reception of a form. Nonetheless, the sense power is a subject and thus matter in an analogous sense.

In his interpretation of Aristotle's *De anima* Thomas defends a view that was as contested in his own time as it is almost an orphan in our own. Among the tenets of so-called Latin Averroism was the view, first held by Averroes, that the move from perceptive acts to intellection is not one from a lower to a higher set of capacities or faculties of the human soul. When Aristotle contrasts intellection with perception and argues that the former does not employ a sense organ because it displays none of the characteristics of perception which does employ an organ, he is not, on the Latin-Averroistic view, referring to another capacity of the human soul, the intellect, but rather referring to a separate entity thanks to whose action human beings engage in what we call thinking. But the cause of this, the agent intellect, is not a faculty of the soul. (Aristotle distinguished two intellects, a passive and an active.) The proof for immortality which results from a wholly immaterial activity is therefore a statement about the incorruptibility of the separate entity, not a basis for arguing that each human soul is immortal because it has the capacity to perform immaterial activities. The Latin-Averroists consequently denied that Aristotle taught personal immortality.

Given this consequence, Thomas's adoption of the opposite interpretation -- viz. that the agent intellect is, like the passive intellect, a faculty of the human soul -- may seem merely an interested desire to enlist Aristotle's support for a position in harmony with Christian belief. Thomas is frequently said to have baptized Aristotle, which seems to mean that he fitted him to the Procrustean bed of Christian doctrine. Of course, the full Christian view is not simply that the soul survives death but that it will be reunited with

body, and Thomas nowhere suggests that there is any intimation of this in Aristotle. Oddly enough, it is often friends of St. Thomas who suggest that he *used* Aristotle and was not chiefly concerned with what Aristotle might actually have intended.

Surely this is libelous. It would be less of an accusation to say that Thomas got a passage wrong than that he pretended it meant something he knew it did not. But the important point, all these centuries later, is whether Thomas's reading is or is not supported by the text. When he commented on the *De anima*, he seems not to be concerned with the flare up in Paris over Latin Averroism. This is the basis for dating the commentary in 1268, before Thomas returned to Paris. The commentary, accordingly, cannot be read as though it were prompted by the controversy. Of course, Thomas might be said to have long term interests in taming Aristotle to behave in a Christian way. As it happens, during the second Parisian period, in the thick of the Latin-Averroist controversy, Thomas wrote an opusculum dedicated to the question: what did Aristotle actually teach? The work is called in the Latin, *De unitate intellectus contra averroistas*. I have translated it as, *On there being only one intellect*. This little work is absolutely essential for assessing the nature of Thomas's Aristotelianism. He provides us with an extended textual analysis to show that the rival interpretation cannot be sustained by the text and that the only coherent reading of the *De anima* must view the agent and passive intellects as faculties of the human soul. His interpretation may be right or wrong, but the matter must be decided on the basis of textual interpretation, not vague remarks about Thomas's intentions.

Beyond Physics

When Aristotle rejected the Platonic Ideas or Forms, accepting some of the arguments against them that Plato himself had devised in the *Parmenides*, he did not thereby reject the notion that the telos of philosophical enquiry is a wisdom which turns on what man can know of God. The magnificent panorama provided at the beginning of the *Metaphysics* as gloss on the claim that all men naturally desire to know rises to and culminates in the conception of wisdom as knowledge of all things in their ultimate or first causes.

For much of the twentieth century, Aristotelian studies have been conducted under the repressive pall of Werner Jaeger's evolutionary hypothesis. On this view, Aristotle began as an ardent Platonist for whom the really real lay beyond sensible reality. With maturity, however, came the sober Macedonian empiricism which trained its attention on the things of this world and eschewed all efforts to transcend it. As for the *Metaphysics*, Jaeger saw it as an amalgam of both theories. The passage just alluded to at the beginning of the work is ascribed to the Platonic phase. Other passages have a far more modest understanding of the range and point of a science over and above natural philosophy and mathematics. *Platonice loquendo*, there are entities which exist separately from sensible things and they constitute the object of the higher science. The more sober view finds a role for a science beyond natural philosophy and mathematics, but it will deal with things those particular sciences leave unattended, e.g. defense of the first principle of reasoning. But these tasks do not call for, and do not imply, a range of beings over and above sensible things.

Jaeger found both these conceptions of metaphysics clumsily juxtaposed in a crucial passage of Book Six.

> One might indeed raise the question whether first philosophy is universal, or deals with one genus, i.e. some one kind of being; for not even the mathematical sciences are all alike in this respect, -- geometry and astronomy deal with a certain particular kind of thing, while universal mathematics applies alike to all. We answer that if there is no substance other than those which are formed by nature, natural science will be the first science; but if there is an immovable substance, the science of this must be prior and must be first philosophy, and universal in this way, because it is first. And it will belong to this to consider being *qua* being -- both what it is and the attributes which belong to it *qua* being. (1025a24-33)

Jaeger invites us to see here a monument to a lost hope and an abiding reluctance to bid it a definitive farewell. Aristotle mentions the possibility of an immovable substance, something existing apart from the natural realm. Without such a separate substance, natural philosophy will be first philosophy. If there is such a substance, it will be a kind of being different from material being. The science that studies it will bear on a certain kind of being, immovable substance, immaterial being, not on being as being. It will be a special, not a universal, science. Jaeger sees Aristotle seeking to glue on to the special science the tasks that belong to a universal science, to make a theology into an ontology.

Jaeger's hypothesis, which cannot withstand half an hour's scrutiny, dominated interpretations of the *Metaphysics* until yesterday. Giovanni Reale's book had to await English translation before it could have any impact. By that time, people were turning from Jaeger and toward Aristotle neat, but this was only to weary of Jaeger, not to disprove him. Thomas's reading of the *Metaphysics* makes clear how mistaken Jaeger's claims are.

But let us first lay out Thomas's view of metaphysics. His question is Aristotle's: is there any science beyond natural science and mathematics? If to be and to be material are identical, then the science of being as being will be identical with the science of material being. That is what Aristotle rejects in the passage just quoted. It is in the course of doing natural philosophy that one gains certain knowledge that not everything that is is material. At the end of the *Physics*, Aristotle argues from the nature of moved movers that they require a first unmoved mover. If successful, this proof establishes that there is a first mover of all moved movers which is not itself material. Furthermore, the discussion of intellect in *On the Soul III* to which we alluded in the preceding paragraph, points beyond the material world. If the activity of intellect provides a basis for saying that, while the human soul is the substantial form of the body, it can exist apart from the body, that is, survive death, it is an immaterial existent. The Prime Mover and the immortal souls of human beings entail that to be and to be material are not identical. Since these are acquisitions at the limit of natural philosophy, they represent possible objects of inquiry in their own right. This is pre-eminently the case with the Prime Mover. It seems inevitable that there should be a discipline whose principal aim is to know more about the divine. How can it be described?

By common consent, Thomas's early discussion of the way theoretical sciences are distinguished from one another in the course of his exposition of the tractate of Boethius *On the Trinity* is masterful. The text speaks of three kinds of theoretical science, physics, mathematics and theology, and Thomas invokes the

methodology of the *Posterior Analytics*. A *scientia* is constituted by a demonstrative syllogism. From a formal point of view, a conclusion follows necessarily from the premises in a well-formed syllogism. Still the conclusion may state a merely contingent truth. What is needed in a demonstrative syllogism is not just the necessity of the consequence but a necessary consequent, and this requires that the premises express necessary truths. That which is necessary cannot be otherwise than as it is; it cannot change. Science thus requires that it bear on immobile things. There is another requirement of the object of speculative or theoretical knowledge which stems from intellection. The activity of the mind, as has been mentioned, is not a material event; it is immaterial. Since it is the mind that knows, science is a mode of its knowing, and will share its nature. Thomas thus states two essential characteristics of the object of speculation, the *speculabile*: it must be removed both from matter and from motion. If that is the case then insofar as there are formally different ways in which *speculabilia* can be removed from matter and motion, there will be formally different speculative sciences.

By this analysis, Thomas has provided the necessary background for understanding the text of Boethius but also more importantly that of Aristotle as it is developed in the chapter from which Werner Jaeger quoted in order to display the failure of the Aristotelian project. "Now we must not fail to notice the nature of the essence and of its formula, for, without this, inquiry is but idle. Of things defined, i.e. of essences, some are like snub, and some like concave. And these differ because snub is bound up with matter (for what is snub is a concave *nose*), while concavity is independent of perceptible matter." (1025a28-32) The objects of natural philosophy are defined like ‘snub’ and the objects of mathematics like ‘concave’. This makes it clear that the way in which natural things are separated from sensible matter is the way in which the definition common to many things abstracts from the singular characteristics of each. But it is the matter as singular that is the principle of change in things, so the common definition has the requisite necessity for science. This or that man comes to be, but what-it-is-to-be-a-man does not come to be or pass away.

Mathematical things, on the analogy of ‘concave’, do not have sensible matter in their definitions. Lines, points, numbers, triangles -- these do not have sensible qualities whether stated universally or singularly. The fact that we define mathematicals without sensible matter does not commit us to the view that mathematicals actually exist apart from sensible matter.

In the commentary on Boethius to which reference has been made, Thomas has early on recalled another fundamental aspect of Aristotle's thought. The objects of thought are either simple or complex, where complex means that one thing is affirmed or denied of another. Knowledge of simples is expressed in a definition, that of the complex in a proposition. Thinking of human nature without thinking of singular characters of this man or that is a matter of definition, not of assertion, as if one were denying that human nature is found in singular matter. So too defining mathematicals without sensible matter is not tantamount to the judgment that mathematicals exist apart from sensible matter. These are both instances of abstraction, where abstraction means to think apart what does not exist apart. Thus it is that the question of metaphysics turns on what Thomas calls *separatio*. To separate differs from abstraction in this that separation is expressed in a negative judgment, a proposition: this is not that, that *this* exists apart from *that*. The relevant separation for metaphysics is the negative judgment that to be and to be material are not the same. That is, there are things which exist apart from matter and motion -- not just are defined

without, but exist without matter and motion.

What then is the subject of metaphysics? "Subject" here means the subject of the conclusion of the demonstrative syllogism. The discussion of definition in effect bore on the middle terms of demonstrative syllogisms and the suggestion is that formally different modes of defining, with respect to removal from matter and motion, ground the formal difference between types of theoretical science. The subject of a demonstration in natural philosophy is defined without singular but with common or universal sensible matter; the subject of a mathematical demonstration is defined without any sensible matter. How can the subject of metaphysics be expressed? The possibility of the science depends on our knowing that some things exist apart from matter and motion. Mathematics does not presuppose the separate existence of its objects; metaphysics does. Why not then say that metaphysics deals with things separated from matter and motion, that is, as Jaeger notes, with a particular kind of being? But that is the not the subject ever assigned to this effort by Aristotle. The methodological reasons can be found in chapter 17 of Book Seven of the *Metaphysics*: the subject of a science must always be a complex entity. That is why the subject of this discipline is being as being.

Why should we say that, in our desire to learn more about separate substances, we should take as our subject all the things that are? The short answer is this: in order to be a theology, metaphysics must first be an ontology. Separate substance, divine being, is not directly accessible for our inspection or study. We come upon our first secure knowledge of God in the proof of the Prime Mover. Tantalizingly, once seen as a necessary requirement for there being any moved movers, the Prime Mover does not become a thematic object of inquiry in natural philosophy. One obvious reason for this is that such an entity is not an instance of the things which fall under the scope of the science. Knowledge of it comes about obliquely and indirectly. The same restriction is operative when the philosopher turns his culminating attention to the deity. How can he know more about the first cause of things? If the Prime Mover is known through moved movers as his effects, any further knowledge of him must be through his effects. It is by describing the effect as widely as possible that one seeks to come to a knowledge of the first cause unrestricted by the characteristics of mobile things. That characterization is being as being. The subject of metaphysics is being in all its amplitude in order to acquire a knowledge of the cause of being that will be correspondingly unbounded.

Philosophical and Scriptural Theology

Earlier we indicated the difference between philosophy and theology in the writings of St. Thomas. That distinction takes theology to mean discourse that takes its rise from the revealed truths of the Bible. But there is also a theology which constitutes the defining telos of philosophical inquiry. In the following passage, Thomas contrasts the two theologies in a way which throws light on what was said in the preceding paragraph.

> Thus it is that divine science or theology is of two kinds, one in which divine things are considered not as the subject of the science but as principles of the subject and this is the theology that the philosophers pursue, also called metaphysics. The other considers divine

> things in themselves as the subject of the science, and this is the theology which is treated in Sacred Scripture. They are both concerned with things which exist separately from matter and motion, but differently, insofar as they are two ways in which something can exist separately from matter and motion: first, such that it is of the definition of the things said to be separate, that they can never exist in matter in motion, as God and the angels are said to be separate from matter and motion; second, such that it is not part of their definition that they exist in matter and motion, because they can exist apart from matter and motion, although sometimes they are found in matter and motion, for example, substance, potency and act are separate from matter and motion because they do not require matter in order to exist as mathematicals do, although they can be understood without sensible matter. Philosophical theology treats of things separate in the second way as its subjects and of things separate in the first way as the principles of its subject. But the theology of Sacred Scripture treats of things separate in the first way as its subjects, although in it some things which exist in matter and motion are considered insofar as they are needed to make the divine manifest." (*Exposition of Boethius' On the Trinity*, q. 5, a. 4)

Philosophical theology is not some science distinct from metaphysics; it is simply the name that can be given to metaphysics because it appeals to God as the cause of its subject. This may make it seem that knowledge of God is merely a bonus, a tangential consideration; on the contrary, it is the chief aim of the science. But the divine can only be known indirectly, through its effects. For this reason, metaphysics can be viewed as an extended effort to examine substance in order to come to knowledge of the first cause. And given the principle that we name things as we know then, this can be regarded as a prolonged effort to devise a language with which to speak of God.

Analogous Names

Aristotle spoke of "things said in many ways", a notable instance of which is "being." One of the difficulties with assigning being or being as being as the subject of a science is that a subject must be univocally common to the things that fall under it and being is not univocal but has a plurality of meanings. Aristotle solved this problem with his account of "things said in many ways," by observing that while they have many meanings, these form an ordered set and one of the meanings is primary and regulative. Substance is being in the primary sense and that is why the science of being as being is effectively a science of substance. Thomas's term for such names is analogy: ‘being’ is an analogous term and its primary analogate is substance.

In the crucial middle books of the *Metaphysics* -- Seven and Eight -- we have an analysis of substance which takes off from material substance, which is a compound of matter and form, and arrives at a notion of substance as form alone. This definition does not fit material substance, of course, but it is devised in order to be able to apply the term substance to the immaterial things whose existence has been established in natural philosophy. This extension of names whose natural habitat is sensible things to God is another instance of analogous naming for Aquinas. Names common to God and creature bring out another feature of our knowing insisted upon by both Aristotle and Aquinas. If we ask what the primary analogate of names common to God and creature is, the answer is: the meaning of the term as it applies to creatures.

The word must be refined before it can be applied to God and this means the formation of an extended meaning which leans on the primary meaning for its intelligibility.

Consider the example of ‘wise.’ Both men and God are said to be wise. What can we mean when we say that God is wise? Not the same thing as when we say that Socrates is wise. Socrates became wise and wisdom is a trait which with age and forgetfulness he could lose. Thus to be Socrates and to be wise are not the same thing. But in the case of God, ‘wise’ does not signify some incidental property He might or might not have. This is captured by noting that while we say God is wise, we also say he *is* wisdom. This suffices to indicate the way in which the meaning of the term as applied to God involves negating features of its meaning as it applies to men.

If God is thus named secondarily by the common name, so that the creature is primarily named by it, nonetheless God's wisdom is the cause and source of human wisdom. Ontologically, God is primary and the creature secondary. Names analogously common to God and creature thus underscore the way in which what comes to be known first for us is not first in reality and what is first in reality is not first in our knowledge.

Essence and Existence

It is evident that material substances exist contingently. They come into being and they pass out of being and while they exist, existence is not what they are. Thomas accepts from Boethius that it is self-evident that what a thing is and for it to exist differ (*diversum est esse et id quod est*). Material things depend upon causes to exist, both to become and to be. There is no need to dwell on this except insofar as it provides a springboard to speak of immaterial substance. Only in God is it the case that what he is and that he is are identical: God is existence. The phrase Thomas uses to express this is *ipsum esse subsistens*. Of course this is paradoxical. Existence is the actuality of a substance, not itself something subsistent. This is true with material substances, but when we ask what we mean by saying that God exists, we have to negate aspects of material existence in order to avoid speaking of Him as if he were a contingent being.

The problem that Thomas now faces is how to speak of the immaterial substances which are less than God although superior to material substances, that is, angels. For a material thing to exist is for its form actually to inhere in its matter. But what is it for a pure form to exist? Since immaterial substances less than God are dependent on the divine causality in order to exist, existence cannot be what they are, of their essence. In short, in angels too there is a distinction of essence and existence. Thomas notes that a created separate substance is what it is and not another thing: that is, it has the perfection it has, but not unlimited perfection. It is a being of a kind, not being as such. Gabriel is perfect as to Gabrielitas, but he is not Raphael or Michael. Form thus operates as a restriction on existence as such. In God alone is there unrestricted existence; he is existence, *ipsum esse subsistens.*

Moral Doctrine

When Aristotle sought to isolate the human good, he employed the so-called function argument. If one know what a carpenter is or does he has the criteria for recognizing a good carpenter. So too with bank-tellers, golfers, brain surgeons and locksmiths. If then man as such has a function, we will have a basis for deciding whether someone is a good human being. But what could this function be? Just as we do not appraise carpenters on the basis of their golf game or golfers on the basis of their being able to pick locks, we will not want to appraise the human agent on an incidental basis. So too we do not appraise the carpenter in terms of his weight, the condition of his lungs or his taste buds. No more would we appraise a human being on the basis of activities he shares with non-humans. The activity that sets the human agent apart from all others is rational activity. The human agent acts knowingly and willingly. If this is the human function, the human being who performs it well will be a good person.

Many have come to this point, pulse quickened by the possibilities of the function-argument, only to be gripped with doubt at this final application of it. Rational activity seems too unmanageable a description to permit a function-analysis of it. Of course Aristotle agrees, having made the point himself. Rational activity is said in many ways or, as Thomas would put it, it is an analogous term. It covers an ordered set of instances. There is the activity of reason as such, there is the activity of reason in its directive or practical capacity, and there are bodily movements and the like which are rational insofar as they are directed by reason. If the virtue of a function is to perform it well, the analogy of "rational activity" makes clear that there is a plurality of virtues. Moral virtues are habits of appetite brought about by the direction of reason. Temperance is to seek pleasure rationally, courage is to react to the threat of harm rationally. The virtues of practical intellect are art and prudence; the virtues of theoretical intellect are insight, science and wisdom.

All this and much more enters into Thomas's moral teaching. Here as elsewhere the Aristotelian component looms large. Thomas will distinguish acts of a man from human acts, the former being activities truly found in human agents but also found in other non-human agents too. The human act is one which proceeds from knowledge and will. Since the human act by definition is the pursuit of a known good, the question arises as to the relationship between the objects of the myriad acts that human perform. Is there some over-all good sought by human agents? Is there an ultimate end of human action?

In commenting on chapter two of Book One of the *Nicomachean Ethics* where Aristotle argues for there being an ultimate end, Thomas points out that the argument is actually a series of *reductiones ad absurdum*. That is, the denial of an ultimate end of human action reduces to the claim that there is no end to human seeking, that it is pointless. This analysis has not gotten the attention it deserves: the implication is that it is self-evident that there is an ultimate end which is why denials of it must flounder in incoherence. The argument for ultimate end that Thomas puts forth in the *Summa theologiae* is somewhat different. Any action aims at some good. A particular good by definition shares in and is not identical with goodness itself. What binds together all the acts that humans perform is the overarching goodness they seek in this, that and the other thing. That over arching goodness, what Thomas calls the *ratio bonitatis*, is the ultimate end. It follows that anything a human agent does is done for the sake of the ultimate end.

This dissatisfies because we feel we are owed a richer account of goodness. After all, human agents differ

insofar as they have different notions of what goodness is. Fame, wealth, pleasure, power, and so on seem to function as the dominant purpose of different persons. Thomas could scarcely overlook this, let alone deny it. Can his earlier position on the unity of the ultimate end still stand? The fact that there are false or inadequate identifications of goodness does not mean that there is not a true and adequate account of what is perfecting or fulfilling of human agents. Everyone acts on the supposition that what he does will contribute to his overall good; one's overall good is the ultimate reason for doing anything. But not everything one does under this aegis actually contributes to one's overall good. Thus in one sense there is one and the same ultimate end for every human agent -- the integral human good -- and there are correct and mistaken notions of what actually constitutes this integral good.

This may seem like an empty claim, but it provides a basis on which to proceed. If indeed every human agent acts for the sake of his overall good, the discussion can turn to whether or not what he here and now pursues, or his general theory of what constitutes the overall good, can withstand scrutiny. It is not necessary to persuade anyone that he ought to pursue the ultimate end in the sense of his overall good. What else would he pursue? But if one is persuaded that what he pursues does not contribute to his overall good, he already has reasons for changing his ways.

Natural Law

Thomas's reading of Aristotle's argument for the ultimate end as a *reductio* and his own claim that in one sense of it everyone pursues the ultimate end since one chooses whatever he chooses *sub ratione boni* and as conducive to or a constituent of his fulfillment and perfection, tell us something important about Thomas's mode of procedure. We said earlier that philosophy begins from pre-philosophical principles already had by everyone. In the moral order, it is essential that one uncover the starting point, the latent assumption of any action, clarify it and proceed from there. This procedure is equally manifest in Thomas's treatment of what he calls natural law.

What is natural law? One description of it is: the peculiarly human participation in the eternal law, in providence. All creatures are ordered to an end, have natures whose fulfillment is what it is because of those natures. It is not peculiar to man that he is fashioned so as to find his good in the fulfillment of his nature. That is true of anything. But others things are ordered to ends of which they themselves are not conscious. It is peculiar to man that he becomes aware of the good and freely directs himself to it. Of course man is not free to choose the good -- any choice is a choice of the good. But as to what is really as opposed to only apparently his good, he is not free to make that what it is. He is free to direct himself or not to his true end, however.

A second description of natural law is: the first principles or starting points of practical reasoning. To indicate what he means by this, Thomas invokes the analogy of the starting points of reasoning as such. We have already mentioned the distinction between knowledge of the simple and knowledge of the complex. The former is a concept and is expressed in a definition or description. The latter is an affirmation or negation of one thing of another. There is something which is first in each of these orders. That is, Thomas holds that there is a conception which is prior to and presupposed by all other conceptions and a judgment that is prior to and presupposed by all other judgments. Since knowledge is

expressed by language, this seems to come down to the assertion that there is a first word that everyone utters and a first sentence that would appear in everyone's baby book on the appropriate page. But surely that is false. So what does Thomas mean?

He says that our first conception is of being, of that which is, and our first judgment is that you cannot affirm and deny the same thing in the same sense simultaneously. Since few if any humans first utter ‘being’ or its equivalent and no one fashions as his first enunciation the principle of contradiction, facts as known to Thomas as ourselves, his meaning must be more subtle. It is this. Whatever concept one first forms and expresses verbally -- Mama, hot, whatever -- is a specification or an instance of that which is. Aristotle has observed that children at first call all men father and all women mother. The terms then function as generic for any male or female. Even more basically, each presupposes that what is generically grasped is an instance of being. Being is prior not because it is grasped absolutely, without reference to this being or that. It is some particular being that is first of all grasped and however it is named it will mean minimally something that is.

So too with regard to the first judgment. Children express their recognition of this principle when they disagree over the location of some quite specific thing, say a baseball mitt. One accuses the other of taking it. You did. I didn't. You did. I didn't. A fundamental disagreement. But what they are agreed on is that if it were true that one did it could not simultaneously and in the same sense be true that he did not. The principle is latent in, implicit in, any concrete judgment just as being is involved in any other conception.

It is on an analogy with these starting points of thinking as such that Thomas develops what he means by natural law. In the practical order there is a first concept analogous to being in the theoretical order and it is the good. The good means what is sought as fulfilling of the seeker. The first practical judgment is: the good should be done and pursued and evil avoided. Any other practical judgment is a specification of this one and thus includes it. Natural Law consists of this first judgment and other most general ones that are beyond contest. These will be fashioned with reference to constituents of our complete good -- existence, food, drink, sex and family, society, desire to know. We have natural inclinations to such goods. Natural law precepts concerning them refer the objects of natural inclinations to our overall or integral good, which they specify.

Most moral judgments are true, if true, only by and large. They express means to achieve our overall good but because there is not a necessary connection between the means and end, they can hold only for the most part. Thus there are innumerable ways in which men lead their lives in keeping with the ultimate end. Not all means are necessarily related to the end. Moral philosophy reposes on natural law precepts as common presuppositions, but its advice will be true only in the main.

It might be noted that when Thomas, following Aristotle, says that man is by nature a social or political animal, he does not mean that each of us has a tendency to enter into social contracts or the like. The natural in this sense is what is not chosen, but given, and what is given about human life is that we are born into the community of the family and are dependent on it for years in order to survive. The moral consists in behaving well in this given setting.

Thomism

Thomas's teaching came under attack, largely by Franciscans, immediately after his death. Dominicans responded. This had the effect of making Dominicans Thomists and Franciscans non-Thomists -- Bonaventurians, Scotists, Ockhamists. The Jesuits were founded after the Reformation and they tended to be Thomists, often with a Suarezian twist.

When in 1879 Leo XIII issued the encyclical *Aeterni Patris* calling for the revival of the study of Thomas Aquinas, he was not directing his readers to one school as opposed to others. Thomas was put forward as the paladin of philosophy in its true sense, as over and against the vagaries of modern thought since Descartes. The response to Leo's call was global and sustained. New journals and learned societies were founded, curricula were reshaped to benefit from the thought of Thomas and this not simply in seminaries and pontifical universities but throughout the world in colleges and universities. Such giants as Jacques Maritain and Etienne Gilson may be taken to symbolize the best of this Thomistic revival.

Vatican II, the ecumenical council that met from 1962-1965 spelled the end of the Thomistic Revival. It was widely held that the Council had dethroned Thomas in favor of unnamed contemporary philosophers. (When they were named, quarrels began.) In the post-conciliar period, Catholics have managed to board every sinking ship in sight and now with the vogue of the notion that modernity has failed and the Enlightenment Project come a cropper, many, Catholics and others, are turning to Thomas as a spur or foil for their thinking. In 1998 John Paul II issued an encyclical called *Fides et Ratio* which may be regarded as the charter of the Thomism of the third millennium.

Jacques Maritain

Jacques Maritain (1882-1973), French philosopher and political thinker, was one of the principal exponents of Thomism in the twentieth century and an influential interpreter of the thought of St Thomas Aquinas.

Life

Jacques Maritain was born on November 18, 1882 in Paris. The son of Paul Maritain, a prominent lawyer, and Geneviève Favre, daughter of the French statesman, Jules Favre, Jacques Maritain studied at the Lycée Henri IV (1898-99) and at the Sorbonne, where he prepared a *licence* in philosophy (1900-1901) and in the natural sciences (1901-1902). He was initially attracted to the philosophy of Spinoza. Largely at the suggestion of his friend, the poet (and, later, religious thinker) Charles Péguy, he attended lectures by Henri Bergson at the Collège de France (1903-1904) and was briefly influenced by Bergson's work.

In 1901, Maritain met Raïssa Oumansoff, a fellow student at the Sorbonne and the daughter of Russian Jewish immigrants. Both were struck by the spiritual aridity of French intellectual life and made a vow to commit suicide within a year should they not find some answer to the apparent meaninglessness of life. Bergson's challenges to the then-dominant positivism sufficed to lead them to give up their thoughts of suicide, and Jacques and Raïssa married in 1904. Soon thereafter, through the influence of the writer Léon Bloy, both Maritains sought baptism in the Roman Catholic Church (1906).

Maritain received his *agrégation* in philosophy in 1905 and, late in 1906, Jacques and Raïssa left for Heidelberg, where Jacques continued his studies in the natural sciences. They returned to France in the summer of 1908, and it was at this time that the Maritains explicitly abandoned *bergsonisme* and Jacques began an intensive study of the writings of Thomas Aquinas.

In 1912, Maritain became professor of philosophy at the Lycée Stanislaus, though he undertook to give lectures at the Institut Catholique de Paris. He was named Assistant Professor at the Institut Catholique (attached to the Chair of the History of Modern Philosophy) in 1914. (He became full Professor in 1921 and, in 1928, was appointed to the Chair of Logic and Cosmology, which he held until 1939.)

In his early philosophical work (e.g., "La science moderne et la raison," 1910, and *La philosophie bergsonienne*, 1913), Maritain sought to defend Thomistic philosophy from its Bergsonian and secular opponents. Following brief service in the first world war, Maritain returned to teaching and research. The focus of his philosophical work continued to be the defense of Catholicism and Catholic thought (e.g., *Antimoderne* [1922], *Trois réformateurs -- Luther, Descartes, Rousseau* [1925], and *Clairvoyance de Rome par les auteurs du 'Pourquoi Rome a parlé' (J. Maritain et D. Lallement)* [1929]), but Maritain also prepared some introductory philosophical texts (e.g., *Éléments de philosophie* [2 volumes, 1921-23]) and his interests expanded to include aesthetics (e.g., *Art et scholastique*, 1921; 2nd ed. 1927).

By the late 1920s, Maritain's attention began to turn to social issues. Although he had some contact with the Catholic social action movement, Action Française, he abandoned it in 1926 when it was condemned by the Catholic Church for its nationalistic and anti-democratic tendencies. Still, encouraged through his friendships with the Russian philosopher Nicholas Berdiaev (beginning in 1924) and Emmanuel Mounier (from 1928), Maritain began to develop the principles of a liberal Christian humanism and defense of

natural rights.

Maritain's philosophical work during this time was eclectic, with the publication of books on Thomas Aquinas (1930), on religion and culture (1930), on Christian philosophy (1933), on Descartes (1932), on the philosophy of science and epistemology (*Distinguer pour unir ou les degrés du savoir*, 1932; 8th ed., 1963) and, perhaps most importantly, on political philosophy. Beginning in 1936, he produced a number of texts, including *Humanisme intégral* (1936), *De la justice politique* (1940), *Les droits de l'homme et la loi naturelle* (1942), *Christianisme et démocratie* (1943), *Principes d'une politique humaniste* (1944), *La personne et le bien commun* (1947), *Man and the State* (written in 1949, but published in 1951), and the posthumously published *La loi naturelle ou loi non-écrite* (lectures delivered in August 1950).

Maritain's ideas were especially influential in Latin America and, largely as a result of the ‘liberal’ character of his political philosophy, he increasingly came under attack from both the left and the right, in France and abroad. Lectures in Latin America in 1936 led to him being named as a corresponding member of the Brazilian Academy of Letters, but also to being the object of a campaign of vilification.

By the early 1930s Maritain was an established figure in Catholic thought. He was already a frequent visitor to North America and, since 1932, had come annually to the Institute of Mediaeval Studies in Toronto (Canada) to give courses of lectures. With the outbreak of war at the end of 1939, Maritain decided not to return to France. Following his lectures in Toronto at the beginning of 1940, he moved to the United States, teaching at Princeton University (1941-42) and Columbia (1941-44).

Maritain remained in the United States during the war, where he was active in the war effort (recording broadcasts destined for occupied France and contributing to the Voice of America). He also continued to lecture and publish on a wide range of subjects -- not only in political philosophy, but in aesthetics (e.g., *Art and Poetry*, 1943), philosophy of education, and metaphysics (*De Bergson à St Thomas d'Aquin*, 1944). Following the liberation of France in the summer of 1944, he was named French ambassador to the Vatican, serving until 1948, but was also actively involved in drafting the United Nations Universal Declaration of Human Rights (1948).

In the spring of 1948, Maritain returned to Princeton as Professor Emeritus, though he also lectured at a number of American universities (particularly at the University of Notre Dame and the University of Chicago), and frequently returned to France to give short courses in philosophy -- notably at ‘L'Eau vive,’ in the town of Soisy, near Paris. During this time, in addition to his work in political philosophy (cf. above, as well as *Le philosophe dans la cité*, 1960), Maritain published on aesthetics (*Creative Intuition in Art and Poetry*, 1953), religion (*Approches de Dieu*, 1953), moral philosophy (*Neuf leçons sur les notions premières de la philosophie morale*, 1951; *La philosophie morale*, 1960), and the philosophy of history (*On the Philosophy of History*, 1957).

In 1960, Maritain and his wife returned to France. Following Raïssa's death later that year, Maritain moved to Toulouse, where he decided to live with a religious order, the Little Brothers of Jesus. During this time he wrote a number of books, the best-known of which was *Le paysan de la Garonne* (a work

sharply critical of post-Vatican Council reforms), published in 1967. In 1970, he petitioned to join the order, and died in Toulouse on April 28, 1973. He is buried alongside Raïssa in Kolbsheim (Alsace) France.

General Background

Maritain saw himself as working in continuity with the thought of Thomas Aquinas, and his writings frequently contain quotations from and references to Thomas' texts. While his turn to Catholicism and his intellectual itinerary were largely due to personal reasons and to the influence of friends, his defense of Catholic thought and Thomistic philosophy were undoubtedly affected by events involving his adopted church.

One such event was the attack on (principally Catholic) religious organisations by secular and humanist forces within the French state, culminating in a number of laws affecting the taxation and ownership of church property and the place of religion in public affairs. At about the same time, there were tensions within Catholicism -- particularly in France -- in reaction to theological modernism. The writings of George Tyrell in England and Ernest Renan and Alfred Loisy in France were condemned for such ‘errors’ as claiming that conscience is the primary source of religious truth and that all knowledge -- including dogma -- has a historical and contingent character, and challenging the authoritative character of magisterial pronouncements. French philosophy itself was seen as incompatible with Catholic theology. The dominant views were the spiritualism or intuitionism of Bergson (which held that the emphasis in metaphysics on ‘being’ should be replaced by one on *durée* or pure change), the idealism of Léon Brunschvicg, the spiritualism of André Lalande, and the materialism of Edmond Goblot -- and each challenged claims that were seen as essential to Catholicism. The Catholic Church in France was, not surprisingly, in some turmoil, and a defense of religious orthodoxy was called for from several quarters.

Maritain's early writings, then, sought to address some of the concerns arising out of these events. Having been attracted initially to Spinoza's idealism and, later, to Bergson's vitalist intuitionism, he was able to come to the defense of Catholic thought with a knowledge of its critics that surpassed many of his contemporaries. Maritain rejected ‘modernity’ -- Cartesian and post-Cartesian thought -- for what he saw as its emphasis on epistemology over metaphysics, and sought to return to the ‘pre-modern’ views of Aquinas. Nevertheless, he saw that philosophy had to do more than merely repeat Thomas' views, and he took it upon himself to develop some aspects of Thomistic philosophy to address the problems of the contemporary world. Thus, though the most profound inspiration of many of Maritain's ideas was the work of St Thomas Aquinas, his epistemology and aesthetics show the influence of Christian mysticism, particularly that of St John of the Cross, and his social and political philosophy clearly reflects many of the ideals of European liberalism.

Principal Contributions

Epistemology

Maritain's primary work in epistemology is *Distinguer pour unir: ou, les degrès du savoir* [*Distinguish to Unite: or, The Degrees of Knowledge*] (1932), though one finds a number of important essays on the topic in *Raison et raisons, essais détachés* [*The Range of Reason*] (1948) and in *Quatre essais sur l'esprit* (1939). He largely follows the realist view of St Thomas Aquinas -- though he was also influenced by St John of the Cross and St Augustine, and the structure of *Les degrès du savoir* appears to reflect the procedure traced in the *Itinerarium mentis in Deum* [*The Journey of the Mind to God*] of St Bonaventure.

Against 'modern philosophy', Maritain insisted on the priority of metaphysics over epistemology -- in fact, he held that "the critique of knowledge is part of metaphysics" [*The Range of Reason*, p. 25] -- and also maintained that the structure and method of the various sciences were determined by the nature of the object to be known.

Maritain called his view critical realism, and argued particularly against the then-dominant rationalist and empiricist accounts of knowledge. He maintained that, despite the differences among them, Kantianism, idealism, pragmatism, and positivism all reflect the influence of nominalism -- that universal notions are creations of the human mind and have no foundation in reality. Maritain's critical realism holds that what the mind knows is identical with what exists. To know a thing is for its 'essence' to exist immaterially in the mind. This is not to say that the mind mirrors or copies that which it knows, but that, in virtue of the properties apprehended, it 'becomes' the things it knows. Maritain held that our knowledge of reality was through the 'concept' -- the *esse intentionale* -- which was immaterial and universal, though the concept itself was something known only by reflection. Thus, when it comes to knowledge of sensible objects, for example, the mind has both a passive role (receiving sense impressions) and an active one (constructing knowledge from these impressions).

Maritain's epistemology sought to explain not just the nature of knowledge found in science and philosophy, but religious faith and mysticism, and one of his aims was to show the different 'kinds' of knowledge and their relations to one another. He argued that there were different 'orders' of knowledge and, within them, different 'degrees' determined by the nature of the object to be known and the 'degree of abstraction' involved.

First, in the order of rational knowledge, one can speak of the knowledge of sensible nature (i.e., of the objects of experimental science), which is different from the knowledge of mathematics or of 'physico-mathematical' objects (which is limited because its objects do not have a direct relation to the actual), which is, in turn, distinct from the knowledge of trans-sensible or metaphysical nature.

These 'degrees of knowledge' are not, however, independent of one another, and they have in common the requirement that to know something is *to know why* it is -- "the mind is not satisfied when it merely attains a thing [...], but only when it grasps that upon which that datum is founded in being and intelligibility" (*Degrees of Knowledge*, p. 23). For example, natural science, which is based on sense perception, aims at formulating laws which reflect certain features of the objects perceived. The scientist, then, is primarily concerned with looking for regularities in nature and in pursuing the empiriological

method of engaging in observation, articulating a hypothesis, and then engaging in further testing; this Maritain calls *perinoetical* knowledge.

But for natural science to achieve the status of a science, it must presuppose natural philosophy -- that is, our capacity to know things apart from their particular individuating characteristics (though not apart from the existence of matter). Natural philosophy ‘gets behind’ phenomena in order to discover essential connections and causes. Thus, from that which is presented in sense perception, the mind constructs an object which is universal. (This is possible because, Maritain maintains, there are essences or natures of things.) This process of ‘thinking through’ to the nature of the thing is called by Maritain *dianoetical* knowledge. While natural science and natural philosophy both focus on the physical, the natural philosopher -- unlike the scientist -- is concerned with the essence of the object and its definition (or, at the very least, an account of its various properties). This, then, is knowledge at the level of the first ‘degree of abstraction.’

Physico-mathematical objects (e.g., quantity, number, and extension) stand at a second level of abstraction. While they cannot exist without the existence of material things, once known, they can be conceived of without any reference to such objects. Metaphysical or speculative knowledge deals with objects existing at a third level of abstraction (i.e., independently of matter), such as substance, quality, goodness, and the divine. Because of the nature of the objects of metaphysics, this latter kind of knowledge does not involve logical inference as much as reasoning by analogy or what Maritain calls *ananoetic* knowledge. Such knowledge (e.g., of the divine) is not through any direct apprehension, but indirectly, through creatures.

There is a hierarchy among these ‘degrees of knowledge.’ Those objects which are highest in intelligibility, immateriality, and potential to be known are the objects of the highest degree of knowledge. Maritain writes, "[t]he metaphysician considers an object of knowing of a specifically higher nature and intelligibility, and from it he acquires a proper knowledge, a scientific knowledge, by means that absolutely transcend those of the physicist or the mathematician" (*Degrees of Knowledge*, p. 37). Nevertheless, one should not conclude that there are different ‘knowledges.’

Maritain points out that philosophical demonstration is different from natural scientific or mathematical demonstrations: "philosophy is concerned with an objectively distinct field of knowledge and constitutes a really autonomous discipline, possessing its own adequate means of explaining this field of knowledge" (*Range of Reason*, p. 5). Specifically, Maritain writes, natural philosophy penetrates to the nature of its object. Metaphysics -- which is also a kind of philosophic knowing -- is concerned with purely intelligible being. Science, however, is at best ‘empiriological’ -- it does not lead us to being itself, but only to the observable and measurable. Thus, to employ a method of scientific demonstration to establish, or to criticize, claims about the object of metaphysical knowledge is, to use Ryle's classic term, a category mistake. And it is precisely because he holds that empiricist and Enlightenment epistemology do this that Maritain takes issue with them.

Just as there is an order of rational knowledge, with its ‘degrees,’ there are degrees of suprarational

knowledge -- of a higher wisdom -- that is beyond ‘natural knowledge.’ These are, on the one hand, ‘the science of revealed mysteries’ or ‘theological wisdom’ and, on the other, ‘mystical theology.’ Here, Maritain's debt to Augustine and John of the Cross is particularly evident. According to Maritain, in theological wisdom, the divine is known by drawing not just on reason but on faith. (This is distinct from metaphysical knowledge which, so to speak, approaches the divine from the ‘outside.’) Mystical knowledge stands one level higher still -- where there is no mediation by concepts -- and "consists in knowing [...] Deity as such -- *according to a mode that is suprahuman and supernatural*" (*The Degrees of Knowledge*, p. 253). This is a knowledge by connaturality, but also a knowledge that can be pursued through the practical discipline of ‘mystical contemplation.’ In this way, human beings acquire a kind of knowledge that makes them more loving and more spiritual.

A number of questions have been raised concerning Maritain's epistemology, particularly concerning his characterization of philosophical knowledge. For example, while Maritain suggests that there is a difference in method between the sciences and philosophy, it is not clear what exactly that difference is. For example, Maritain would follow Aquinas in holding that metaphysics uses *demonstratio quia* -- demonstration from effects. But it would seem that science also sometimes uses such a method of demonstration. Indeed, it is not clear what it is in the *method* (as distinct from the content of the premises) that differentiates a metaphysical proof (e.g., of God's existence) from a scientific argument establishing the existence of a cause of a natural object.

Second, Maritain holds that scientific knowledge is distinguished from philosophical knowledge in terms of their different methods and different objects. But if scientific knowledge and philosophical knowledge are, as it were, incommensurable, it is not clear how philosophy can judge, or be corrective of, the sciences.

Finally, it would seem that the model of demonstration that Maritain employs is foundationalist and, thus, has to answer to those criticisms that modern anti-foundationalism draws attention to -- e.g., that a foundationalist theory sets a standard for knowledge that is not only without justification, but is a standard that it cannot itself satisfy. Some recent defences of Thomistic epistemology (e.g., Henry Veatch in *Thomistic Papers*, Volume IV, 1990) suggest ways in which such concerns might be addressed.

Natural Theology and Philosophy of Religion

Like St Thomas Aquinas, Maritain held that there was no conflict between faith and true reason, that religious belief was open to rational discussion, and that the existence of God and certain fundamental religious beliefs could be philosophically demonstrated. Religious belief, then, was not an attitude or a matter of private opinion -- an option that could be embraced or not according to one's private preferences; it was a matter of ‘truth’. For Maritain, one must choose between "the true God or radical irrationality" (*Introduction to Philosophy*, p. 259).

Maritain held that philosophy was an *ancilla theologiae*, and that philosophy, under the rubric of

metaphysical knowledge, allows for the demonstration of a number of basic religious beliefs. And, like Aquinas, Maritain accepted the classical foundationalist position that these beliefs could be established by rational deduction from self-evident principles and constituted genuine knowledge. Specifically, he held that, by the use of natural reason, one can come to know certain truths about God, and that the ‘five ways’ of Thomas Aquinas provided sure knowledge of God's existence. But Maritain also argued that there could be other ‘proofs’ of the existence of the divine and, in *Approches de Dieu*, he developed what he called a "sixth way."

There is, Maritain writes, an intuition that is awakened in persons when they are engaged in thought -- that is, that it seems impossible that they, as thinking beings, should at some time have not been. As a thinking being, one seems to be free from the vicissitudes of time and space; there is no coming to be or ceasing to be -- I cannot think what it is not to be. Nevertheless, we all know very well that we were born -- we came into existence. We are confronted, then, with a contradiction -- not a logical contradiction, but a lived contradiction. The only solution to this is that one has always existed, but not through oneself, but within "a Being of transcendent personality" and from whom "the self which is thinking now proceeded into temporal existence" (*Approches de Dieu*, in *Oeuvres complètes*, p. 64). This being "must contain all things in itself in an eminent mode and be itself -- in an absolutely transcendent way -- being, thought and personality. This implies that the first existence is the infinite plenitude of being, separate by essence from all diversity of existents." (p. 66).

Maritain also acknowledges the possibility of a natural, pre-philosophical, but still rational knowledge of God (see *Approches de Dieu*, pp. 13-22). This is, Maritain claims, a ‘knowledge’ that is necessary to -- and, in fact leads to -- a philosophical demonstration of God's existence. (In this way, then, one can know that some religious beliefs are true, even without being able to demonstrate them.) Maritain's argument, which resembles the Thomistic argument from contingent being, is that, in one's intuition of being, one is aware, first, of a reality separate from oneself, second, of oneself as finite and limited, and, third, of the necessity that there is something "completely free from nothingness and death" (*Approches de Dieu*, p. 15). This is concurrent with a "spontaneous reasoning" that follows the same course to the conclusion that there is "another Whole [...] another Being, transcendent and self-sufficient and unknown in itself and activating all beings [...] that is, self-subsisting Being, Being existing through itself" (*Approches de Dieu*, p. 16). This ‘knowledge’ of God, Maritain admits, is not demonstrative but is, nevertheless, "rich in certitude" (*Approches de Dieu*, p. 19) and is both presupposed by, and is the underlying force for, philosophical demonstrations of God's existence.

The difference between the pre-philosophical and the philosophical ‘knowledge’ of God is that the latter is one which is based on a "scientific demonstration" (*Approches de Dieu*, p. 19) -- on empirical facts -- and involving analogy, from which we have terms that can be properly predicated of the divine. On the other hand, ‘pre-philosophical’ knowledge is "intuition" -- an *approach* to knowledge, though not a "way," (*Approches de Dieu*, p. 20) a proof or a demonstration. This knowledge is based on a natural reasoning which cannot be expressed in words. Yet, it is important also to realize that while Maritain allows that certain ‘truths’ "are grasped by the common sense before being the object of philosophical concern" (*Approches de Dieu*, p. 24), philosophical proofs of the existence of God "are not only established and justified philosophically at the level of philosophy itself, but are already valid and

efficacious at the level of this incohative and spontaneous philosophy," (*Approches de Dieu*, p. 24) and that what one arrives at by means of such an ‘approach’ is (as it is in philosophical demonstrations) knowledge of the truth of a proposition.

It has been argued, however, that there are some difficulties with Maritain's position here. For example, even if it is true that people may ‘naturally’ affirm the proposition that there is a God, it is not obvious how they can claim that they *know* it. In other words, even if the proposition is true, it is not clear how we can say that we know or believe it to be true. What Maritain seems to give us here is an explanation of how one arrives at a certain proposition and of one's certainty, but nothing more. But, since the state of certainty of an individual is not the same as the assertion that that person knows something to be true, it is not clear that the pre-philosophical approach provides one with an adequate basis to say that a religious belief is true, only that one is convinced of it. And, one might argue, parallel conclusions can be drawn if one examines the other ways that Maritain suggests will lead to a putative ‘knowledge’ of God.

(Interestingly, Maritain was a critic of a number of arguments proposed in defence of religious belief. He argued that such defenses fail because they do not recognise that there are different types of knowledge, that these different types are hierarchically arranged, and that the methods they employ are, by definition, unsuited to demonstrate certain things. Thus, Maritain holds that while ‘reason,’ as ‘intelligence moving in a progressive way towards its term, the real’, can attain knowledge of God by means of demonstration, if we take ‘reason’ to be a purely discursive method -- one which Maritain identifies with the "physical-mathematical sciences" and which he also calls "the ‘reason’ of rationalism" (*Antimoderne*, p. 64) -- it can know or say nothing at all about God. Because reason must be ordered to its object, reason (in this second sense) can neither demonstrate nor even encounter revealed truths.)

In addition to the possibility of the demonstration of the existence of God and of the coherence of the divine attributes, Maritain allows that there are a number of other ways in which one might come to ‘know’ religious beliefs to be true. Besides knowing God ‘naturally,’ there is a ‘non-conscious knowledge of God’ in the first act of human freedom (see *Range of Reason*, pp. 69-71), ‘connatural knowledge’ (which is typical of mystical experience), ‘abstract intuition’ (by which one knows ‘primary principles’ such as the laws of identity and of non-contradiction and the principle of causality), the "ways of the practical intellect" (*Approches de Dieu*, ch. IV) (i.e., through moral or aesthetic experience -- though these do not provide a strict demonstration) and, of course, divine revelation.

Nevertheless, Maritain also held that it was reasonable to believe even in the absence of such arguments or evidence. (To say that one can attain, by reason, some knowledge of God is not to say that everyone can do this.) Moreover, Maritain argues that even if one holds that a belief is capable of a rational demonstration, it does not follow that one must be able to provide it. For a religious belief to be ‘reasonable,’ it must not contradict the results of ‘true reason’ but, for one's knowledge of ‘revealed truths’ to be reasonable, Maritain (like Aquinas) would never claim that one must be able to produce a philosophical demonstration of them. In fact, Maritain allows that theology can "reject as false any philosophic affirmation which contradicts a theological truth" (*Introduction to Philosophy*, p. 126).

Maritain writes that there can also be knowledge of the divine attributes. As with all natural knowledge of the divine, this is basically analogical, and it follows a *via negativa*. Thus, he insists that we can say that we know some things about God. We can know that God is (*quia est*), though not what God is in himself (*quid est*) (*Degrees of Knowledge*, Appendix III, p. 423). In fact, against Sertillanges and Etienne Gilson, Maritain maintains that we can have affirmative knowledge about God -- know in a more or less imperfect but, nevertheless, true way what God is. Besides, Maritain holds, knowledge through negation presupposes positive knowledge. Mary Daly notes, however, that Maritain is not clear about the extent to which our affirmative knowledge of God is arrived at by means of philosophical argument (Daly, p. 53). Nevertheless, Maritain acknowledges that the knowledge of God that philosophy provides us with is incomplete and imperfect. The *analogical* knowledge that we have of God falls short of a complete description of what God is.

It is not clear, however, that Maritain avoids many of the concerns expressed by critics of 'analogical knowledge.' For example, if the term 'cause' is used analogously when applied to God, then when one utters the proposition 'God is the cause of the universe' after examining Aquinas's 'second way,' it would seem that one has to be using this term in exactly the same sense as it has been used throughout the preceding argument. If it is not being used in exactly the same sense, then how can one claim that Aquinas has *demonstrated* this conclusion? The problem is not whether analogical predication is possible but, first, whether one can understand the analogical predicate and, second, whether one can employ such a predicate in a demonstration without committing the fallacy of equivocation.

Given Maritain's account of faith and of suprarational knowledge, it would seem that he would see religious beliefs as 'trusts' and, hence, as having more than a purely cognitive character. He would, no doubt, follow Aquinas who spoke of religion as a 'disposition.' A disposition or *habitus* is, of course, not merely the product of action, but itself is ordered to action. Thus, to say that religious beliefs are propositional in form is not to say that their function is only descriptive. Nevertheless, Maritain's account of religious belief and its relation to argument and proof is not complete. Moreover, given that he does employ 'foundationalism' as a standard of sufficient evidence for claiming that some propositions expressing religious belief are true, it is not clear that it can directly address the challenges of recent critics -- particularly those raised by some 'postmodern' philosophers concerning the epistemology underlying his view.

Moral and Political Philosophy and Philosophy of Law

Maritain's moral and political philosophy lies within what may be called the Aristotelian-Thomistic natural law tradition. Maritain held, however, that Aristotelian ethics, by itself, was inadequate because it lacked knowledge of humanity's ultimate end. The Thomistic view -- that there is a law in human nature that is derivative of (though knowable separately from) a divine or eternal law and that humanity's 'end' goes beyond anything attainable in this life -- was, Maritain thought, a significant advance on what Aristotle had provided.

Following Aquinas, Maritain maintained that there is a natural law that is 'unwritten' but immanent in

nature. Specifically, given that nature has a teleological character, one can know what a thing ‘should’ do or how it ‘should’ be used by examining its ‘end’ and the ‘normality of its functioning.’ Maritain therefore defines ‘natural law’ as "an order or a disposition that the human reason may discover and according to which the human will must act to accord itself with the necessary ends of the human being" (*La loi naturelle*, p. 21; see *Man and the State*, p. 86). This law "prescribes our most fundamental duties" (*Man and the State*, p. 95) and is coextensive with morality.

There is, Maritain holds, a single natural law governing all beings with a human nature. The first principles of this law are known *connaturally*, not rationally or through concepts -- by an activity that Maritain, following Aquinas, called ‘synderesis.’ Thus, ‘natural ‘law’ is ‘natural’ because it not only reflects human nature, but is known naturally. Maritain acknowledges, however, that knowledge of the natural law varies throughout humanity and according to individuals’ capacities and abilities, and he speaks of growth in an individual's or a collectivity's moral awareness. This allows him to reply to the challenge that there cannot be any universal, natural law because no such law is known or respected universally. Again, though this law is progressively known, it is never known completely, and so the natural law is never exhausted in any particular articulation of it. This recognition of the historical element in human consciousness did not, however, prevent Maritain from holding that this law is objective and binding. (Critics have argued, however, that to speak of ‘connatural knowledge’ is obscure; it is quite unlike what we ordinarily call ‘knowledge’ and is, therefore, inadequate as a basis for knowledge of law.)

A key notion in Maritain's moral philosophy is that of human freedom. He says that the ‘end’ of humanity is to be free but, by ‘freedom,’ he does not mean license or pure rational autonomy, but the realisation of the human person in accord with his or her nature -- specifically, the achievement of moral and spiritual perfection. Maritain's moral philosophy, then, cannot be considered independently of his analysis of human nature. Maritain distinguishes between the human being as an individual and as a person. Human beings are ‘individuals’ who are related to a common, social order of which they are parts. But they are also persons. The person is a ‘whole’, is an object of dignity, "must be treated as an end" (*Les droits de l'homme*, p. 84) and has a transcendent destiny. In both the material and the spiritual order, however, human beings participate in a ‘common good.’ Thus, one is an individual in virtue of being a material being; one is a person so far as one is capable of intellectual activity and freedom. Still, while distinct, both elements are equally necessary to being a human being. It is in virtue of their individuality that human beings have obligations to the social order, but it is in virtue of their personality that they cannot be subordinated to that order. Maritain's emphasis on the value of the human person has been described as a form of *personalism*, which he saw as a *via media* between individualism and socialism.

Maritain's political philosophy and his philosophy of law are clearly related to his moral philosophy. The position that he defended was described by him in one of his earliest political works as ‘integral Christian Humanism’ -- ‘integral’, because it considers the human Being, an entity that has both material and spiritual dimensions, as a unified whole and because it sees human beings in society as participants in a common good. The object of Maritain's political philosophy was to outline the conditions necessary to making the individual more fully human in all respects. His integral humanism, then, seeks to bring the

different dimensions of the human person together, without ignoring or diminishing the value of either. While one's private good as an individual is subordinate to the (temporal) common good of the community, as a person with a supernatural end, one's ‘spiritual good’ is superior to society -- and this is something that all political communities should recognize.

For Maritain, the best political order is one which recognizes the sovereignty of God. He rejects, therefore, not only fascism and communism, but all secular humanisms. He objects that such views -- particularly fascism and communism -- are not only secular religions, but dehumanizing and, while he was a defender of American-style democracy, he is clearly not interested in combining his attachment to Christianity with capitalism. A theocentric humanism, Maritain would argue, has its philosophical foundation in the recognition of the nature of the human person as a spiritual and material being -- a being that has a relation to God -- and morality and social and political institutions must therefore reflect this.

Maritain envisages a political society under the rule of law -- and he distinguishes four types of law: the eternal, the natural, the ‘common law of civilisation’ (*droit des gens* or *jus gentium*), and the positive (*droit positif*).

The natural law is "universal and invariable" and deals with "the rights and duties which follow [necessarily] from the first principle" (see *Man and the State*, pp. 97-98) or precept of law -- that good is to be done and evil avoided. Nevertheless, while the natural law is "self-evident" (see *Man and the State*, p. 90) and consistent with and confirmed by experience -- something which many critics have challenged -- Maritain holds that it is not founded on human nature. It is rooted in divine reason and in a transcendent order (i.e., in the eternal law), and is ‘written into’ human nature by God. At times, Maritain appears to hold that natural law acquires its obligatory character only because of its relation to the eternal law; he writes that "natural law is law only because it is participation in Eternal Law" (see *Man and the State*, p. 96). (Some have concluded, then, that such a theory must be ultimately theological.)

The *droit des gens* or ‘common law of civilisation’ is an extension of the natural law to the circumstances of life in society, and thus it is concerned with human beings as social beings (e.g., as citizens or as members of families). The ‘positive law’ is the system of rules and regulations involved in assuring general order within a particular society. It varies according to the stage of social or economic development within that community and according to the specific activities of individuals within it. Neither the positive law nor the *droit des gens* is, however, deducible from the natural law alone. Neither is known connaturally and, therefore, is not part of the natural law. Nevertheless, it is in virtue of their relation to natural law that they "have the force of law and impose themselves on conscience" (*Les droits de l'homme*, pp. 90-91). When a positive law acts against the natural law, it is, strictly speaking, not a law. Thus, Maritain clearly rejects legal positivism.

The term ‘natural law’ and its relations both to ‘eternal law’ and to positive law have, however, been the focus of much controversy. Maritain's account of natural law both presupposes a metaphysical view of the nature of human beings and a realistic epistemology, and has a number of tensions or inconsistencies

internal to it. Some of the principal criticisms of this account are i) that it is inconsistent because it sets forth a naturalistic theory of what is good and bad and yet claims that only a supernatural sanction will serve to explain moral obligation, ii) that connatural knowledge is not only inadequate for what we normally count as knowledge, but it is, in fact, also incapable of establishing that something is a natural moral law, iii) that the first principle of moral law is vacuous, and iv) that Maritain glosses over the fact/value distinction.

Maritain held that natural law theory entailed an account of human rights. Since the natural end of each person is to achieve moral and spiritual perfection, it is necessary to have the means to do so, i.e., to have rights which, since they serve to realise his or her nature, are called ‘natural’. This respects the Aristotelian-Thomistic principle of justice, that we should distribute to each ‘what is truly his or hers’. Maritain replies to the criticism that there are no such rights, since they are not universally recognised, by reminding his readers that, just as the natural law comes to be recognised gradually and over time, so also is there a gradual recognition of rights. Indeed, Maritain held that certain basic natural rights can be recognised by all, without there having to be agreement on their foundation and, as an illustration of this, he pointed to the general agreement on those rights found in the 1948 United Nations Declaration of Human Rights.

Maritain held that natural rights are fundamental and inalienable, and antecedent in nature, and superior, to society. Still, they should not be understood as ‘antecedent’ in a temporal sense and do not form the basis of the state or of the civil law. Rights are grounded in the natural law, and specifically in relation to the common good. It is this good, and not individual rights, that is the basis of the state, and it is because of this that Maritain held that there can be a hierarchical ordering of these rights (*Man and the State*, p. 106-107).

One consequence of his natural law and natural rights theory is that Maritain favoured a democratic and liberal view of the state, and argued for a political society that is both personalist, pluralist, and Christianly-inspired. He held that the authority to rule derives from the people -- for people have a natural right to govern themselves. Still, this is consistent with a commitment to Christianity, Maritain thought, because the ideals of democracy are themselves inspired by a belief in God's rule, and that the primary source of all authority is God (*Man and the State*, p, 127).

Maritain also favoured a number of liberal ideals, and the list of rights that he recognises extends significantly beyond that found in many liberal theories, and includes the rights of workers as well as those of the human and the civic person.

Furthermore, the ideal of freedom or liberty to be found in the state is close to that which is now generally called ‘positive freedom’ -- i.e., one that reflects a view of the person as sharing in a common good. As a polity that attempts to provide the conditions for the realisation of the human person as an individual who is, thereby, a member of a temporal community, it recognises that the use of goods by individuals must serve the good of all (*Integral Humanism*, p. 184), and that individuals can be required to serve the community. Moreover, in such a state political leaders would be more than just

spokespersons for the people (*Man and the State*, p. 140), and Maritain recognises that they can represent the ‘hidden will’ of the people. Their aim -- and the aim of the state as a whole -- is, however, always the common good. Since minorities may themselves reflect this ‘hidden will,’ Maritain also recognised the important role to be played by dissenting minorities.

(Maritain does not discuss in any detail how his model ‘Christian’ polity might be realised, but suggests that it is the only one that takes account of each person's spiritual worth and that recognises the importance of providing the means to foster one's growth as a person. It recognises differences of religious conscience and is, in this way, fundamentally pluralistic.)

In such an ideal polity, Maritain imagines that a leadership role would be played by a multiplicity of ‘civic fraternities,’ founded on freedom, inspired by the virtues of Christianity, reflecting a moral and spiritual discipline, and which are fundamentally democratic. While such groups would not necessarily exercise political power, the society as a whole would reflect Christian values -- not just because these values are part of a privileged religion or faith (a matter that Maritain would be wary of), but because these are necessary to the temporal community. In such a polity one would, of course, find a church and a state, though Maritain would see them as cooperative entities, with the state occupying itself with those matters that, while focusing on temporal concerns, addressed the needs of the whole of the human person, and with the church focussing on spiritual matters.

It is, perhaps, evident that such a polity could not survive within a single nation state that existed among a plurality of states with different ideals, and so Maritain supported the ideal of a world federation of political societies. While the realisation of such an ideal was something that lay in a distant future, Maritain nevertheless thought that such a federation was possible, providing that the individual states retained a fair degree of autonomy and that persons could be found from each state who would voluntarily distance themselves from the particular interests of their home country.

General Assessment

At the time of his death, Maritain was arguably the best known Catholic philosopher in the world. The breadth of his philosophical work, his influence in the social philosophy of the Catholic Church, and his ardent defenses of human rights made him one of the central figures of his times.

Maritain's philosophical work has been translated into some twenty languages. As is evident from the preceding remarks, it covers a wide range of areas -- though much of it was written for a general, rather than a professional academic, audience. Still, some of Maritain's writings are polemical and, because much of his concern (especially in the history of philosophy) was to address very specific philosophical and theological issues of his time, they often have a rather dated character.

Maritain's most enduring legacy is undoubtedly his moral and political philosophy, and the influence of his work on human rights can be seen, not only in the United Nations Declaration of 1948 but, it has been

claimed, in a number of national declarations, such as the Canadian Charter of Rights and Freedoms and the preamble to the Constitution of the Fourth French Republic (1946) -- this last was likely a reflection of Maritain's lengthy correspondence with the French war hero and, later, President, General Charles DeGaulle. Maritain's Christian humanism and personalism have also had a significant influence in the social encyclicals of Pope Paul VI and in the thought of Pope John Paul II. Interestingly, since the end of the Cold War, there has been a revival of Maritain's political ideas in Central and Eastern Europe.

Two other areas in which Maritain's thought has been influential are his aesthetics and his philosophy of education. Although no longer as strong as they once were, they were particularly significant in Latin America and French-speaking Africa from the 1930s until recent years. Maritain's work in epistemology, though clearly essential to his political and religious thought and to his aesthetics, has not, however, had the reception Maritain would have held it deserved.

It is, in short, not easy to place Maritain's work within the history of philosophy in the 20th century. Clearly, his influence was strongest in those countries where Thomistic philosophy had pride of place. While his political philosophy led him, at least in his time, to be considered a liberal and even a social democrat, he eschewed socialism and, in *Le paysan de la Garonne*, was an early critic of many of the religious reforms that followed the Second Vatican Council. One can say, then, that he would be considered by present-day liberals as too conservative, and by many conservatives as too liberal. Again, though generally considered to be a Thomist, the extent to which he was is a matter of some debate. Indeed, according to Etienne Gilson, Maritain's ‘Thomism’ was really an epistemology and, hence, not a real Thomism at all. There is, not surprisingly, no generally shared view of the precise character of Maritain's philosophy.

Maritain's work nevertheless remains influential. Since 1958 there has been a Jacques Maritain Center at the University of Notre Dame in the United States, there are journals devoted to his work, such as *Études maritainiennes / Maritain Studies*, *Notes et documents*, and the *Cahiers Jacques et Raïssa Maritain*, and there are currently some twenty national associations which meet regularly, in addition to the *Institut International Jacques Maritain*. The continuity of interest in his thought in the English-speaking world has recently led the University of Notre Dame Press to undertake the publication of a *Collected Works* of the English-language editions of Maritain's writings.

Maritain's Principal Works

A French-language edition of the works of Maritain is available under the title *Oeuvres complètes de Jacques et Raïssa Maritain*, 15 vols., Fribourg (Switzerland): Éditions universitaires, 1982-. The publication of a 20 volume set, in English, of *The Collected Works of Jacques Maritain* (under the general editorship of Ralph McInerny) is currently underway under auspices of the University of Notre Dame Press.

Maritain's principal works are listed below in chronological order: (Except where indicated otherwise, place of publication is Paris. English-language editions are noted as well.)

- *La Philosophie bergsonienne: études critiques*. Marcel Rivière et Cie., 1914. [*Bergsonian Philosophy and Thomism*. New York: Philosophical Library, 1955.]
- *Art et scolastique*. Librairie de l'Art Catholique, 1920. (The 1927 edition contains "Frontières de la poésie" and important notes.) [*Art and Scholasticism and The Frontiers of Poetry*. Tr. Joseph W. Evans. New York: Charles Scribner's Sons, 1962.]
- *Éléments de Philosophie I: Introduction générale à la philosophie*. Téqui, 1920. [*An Introduction to Philosophy*. Tr. E. I. Watkin. London: Sheed and Ward, 1944.]
- *Théonas ou les entretiens d'un sage et deux philosophes sur diverses matières inégalement actuelles*. First publication in the *Revue Universelle*, April 1920 to April 1921, 1st edition, Nouvelle Librairie Nationale, 1921; 2nd edition, corrected, 1925. [*Theonas: Conversations of a Sage*. Tr. F.J. Sheed. London: Sheed and Ward, 1933.]
- *Antimoderne*. Éditions de la Revue des Jeunes, 1922.
- *De la vie d'oraison*. 1st edition privately printed, Saint-Maurice d'Augaune, 1922; 2nd edition revised, l'Art Catholique, 1925. [with Raïssa Maritain] [*Prayer and intelligence*. New York: P. J. Kennedy, 1928.]
- *Éléments de philosophie II: L'ordre des concepts, I - Petite logique (Logique formelle*). Téqui, 1923. [*An Introduction to Logic*. New York: Sheed and Ward, 1937; *Formal Logic*. New York: Sheed and Ward, 1937.]
- *Réflexions sur l'intelligence et sur sa vie propre*. Bibliothèque français de philosophie, Nouvelle Librairie Nationale, 1924, 1926, 1930; Desclée, 1938.
- *Trois Réformateurs: Luther, Descartes, Rousseau*. Librairie Plon, 1925. [*Three Reformers: Luther, Descartes, Rousseau*. New York: Charles Scribner's Sons, 1929.]
- *Georges Rouault, peintre et lithographe*. Éditions Polyglotte, Frapier, 1926. [*George Roualt*. New York: Harry N. Abrams, Inc., in association with Pocket Books, Inc., 1954.]

Liberalism

Liberalism can be understood as (1) a political tradition (2) a political philosophy and (3) a general philosophical theory, encompassing a theory of value, a conception of the person and a moral theory as well as a political philosophy. As a *political tradition* liberalism has varied in different countries. In England --- in many ways the birthplace of liberalism --- the liberal tradition in politics has centred on religious toleration, government by consent, personal and, especially, economic freedom. In France liberalism has been more closely associated with secularism and democracy. In the United States liberals often combine a devotion to personal liberty with an antipathy to capitalism, while the liberalism of Australia tends to be much more sympathetic to capitalism but often less enthusiastic about civil liberties. To understand this diversity in political traditions, we need to examine liberalism as a *political theory* and as a *general philosophy*. These latter two are the concerns of this essay.

Liberalism as a Political Theory

Liberty

'By definition', Maurice Cranston rightly pointed out, 'a liberal is a man who believes in liberty' (Cranston, 459). In two different ways, liberals accord liberty primacy as a political value. First, liberals have typically maintained that humans are naturally in 'a *State of perfect Freedom* to order their Actions...as they think fit...without asking leave, or depending on the Will of any other Man' (Locke, 1960 [1689]: 287). Mill too argued that '[T]he burthen of proof is supposed to ith those who are against liberty; who contend for any restriction or prohibition.... The *a priori* assumption is in favour of freedom...'(Mill, 1991 [1859]: 472). This might be called the **Fundamental Liberal Principle** (Gaus, 1996: 162-166): freedom is normatively basic, and so the onus of justification is on those who would limit freedom. It follows from this that political authority and law must be justified, as they limit the liberty of

citizens. Consequently, a central question of liberal political theory is whether political authority can be justified, and if so, how. It is for this reason that social contract theory, as developed Thomas Hobbes (1948 [1651]), John Locke (1960 [1689]), Jean-Jacques Rousseau (1973 [1762]) and Immanuel Kant (1965 [1797]), is usually viewed as liberal even though the actual political prescriptions of, say, Hobbes and Rousseau, have distinctly illiberal features. Insofar as they take as their starting point a state of nature in which humans are free and equal, and so argue that any limitation of this freedom and equality stands in need of justification (i.e., by the social contract), the contractual tradition expresses the Fundamental Liberal Principle.

The Fundamental Liberal Principle holds that restrictions on liberty must be justified, and because he accepts this, we can understand Hobbes as espousing a liberal political theory. But Hobbes is at best a qualified liberal, for he also argues that drastic limitations on liberty *can be* justified. Paradigmatic liberals such as Locke not only advocate the Fundamental Liberal Principle, but also maintain that justified limitations on liberty are fairly modest. Only a limited government can be justified; indeed, the basic task of government is to protect the equal liberty of citizens. Thus John Rawls's first principle of justice: ‘Each person is to have an equal right to the most extensive total system of equal basic liberties compatible with a similar system for all’ (Rawls, 1971: 302).

Negative and Positive Liberty

Liberals disagree, however, about the concept of liberty, and as a result the liberal ideal of protecting individual liberty can lead to very different conceptions of the task of government. As is well-known, Isaiah Berlin has advocated a negative conception of liberty:

> I am normally said to be free to the degree to which no man or body of men interferes with my activity. Political liberty in this sense is simply the area within which a man can act unobstructed by others. If I am prevented by others from doing what I could otherwise do, I am to that degree unfree; and if this area is contracted by other men beyond a certain minimum, I can be described as being coerced, or, it may be, enslaved. Coercion is not, however, a term that covers every form of inability. If I say that I am unable to jump more than ten feet in the air, or cannot read because I am blind...it would be eccentric to say that I am to that degree enslaved or coerced. Coercion implies the deliberate interference of other human beings within the area in which I could otherwise act. You lack political liberty or freedom only if you are prevented from attaining a goal by other human beings (Berlin, 1969: 122).

For Berlin and those who follow him, then, the heart of liberty is the absence of coercion by others; consequently, the liberal state's commitment to protecting liberty is, essentially, the job of ensuring that citizens do not coerce each other without compelling justification. However, despite the powerful case for negative liberty, many liberals have been attracted to more ‘positive’ conceptions of liberty. Although Rousseau (1973 [1762]) seemed to advocate a positive conception of liberty, according to which one was free when one acted according to one's true will (the general will), the positive conception was best

developed by the British neo-Hegelians of the late nineteenth and early twentieth centuries, such as Thomas Green and Bernard Bosanquet (1923). Green acknowledged that '...it must be of course admitted that every usage of the term [i.e., freedom] to express anything but a social and political relation of one man to other involves a metaphor...It always implies...some exemption from compulsion by another...(1986 [1895]: 229). Nevertheless, Green went on to claim that a person can be unfree if he is subject to an impulse or craving that cannot be controlled. Such a person, Green argued, is '...in the condition of a bondsman who is carrying out the will of another, not his own' (1986 [1895]: 228). Just as a slave is not doing what he *really* wants to do, one who is, say, an alcoholic is being led by a craving to look for satisfaction where it cannot, ultimately, be found.

For Green, a person is free only if she is self-directed or autonomous. Running throughout liberal political theory is an ideal of a free person as one whose actions are in some sense her *own*. Such a person is not subject to compulsions, critically reflects on her ideals and so does not unreflectively follow custom and does not ignore her long-term interests for short term pleasures. This ideal of freedom as autonomy has its roots not only in Rousseau's and Kant's political theory, but in John Stuart Mill's *On Liberty*. And today it is a dominant strain in liberalism, as witnessed by the work of S.I. Benn (1988), Gerald Dworkin (1988), and Joseph Raz (1986).

A continuing problem for liberal theory is whether these two conceptions of freedom can somehow co-exist (Benn, 1988) or whether they are, as Berlin argued, fundamentally at odds. The worry about positive freedom is that it seems to lay the basis for justifying paternalistic interferences *on the grounds that they are freedom-enhancing*. A paternalist imposes on a person for his own good, and typically this imposition would appear to limit that person's freedom. The paternalist stops him from drinking or taking drugs. But if drinking and so on hinders a person from acting autonomously, then this imposition may actually increase his freedom, since it increases his long-term propensity to act autonomously (Young, 1986). Thus, in Rousseau's chilling words, it seems that one can be 'forced to be free' (1973 [1762]: 177).

In any event, those who emphasise positive freedom and autonomy are apt to take a much more expansive view of the job of the liberal state. Benn, for instance, endorses 'rights to the conditions for autonomy' --- 'the rights to such conditions would presumably include the *Universal Declaration* rights to education, to leisure, and to participate in the cultural life of the community...' (1988: 251-52; but cf. Spector, 1992). This sort of welfarist-participatory state is precisely that which many advocates of negative liberty see as a threat to freedom. Thus argues Jan Narveson:

> The trouble with the enthusiast for 'positive liberty' is that to bring about the no doubt excellent goals he professes, he is willing to violate negative liberty. [And]...'positive liberty' might as well be replaced by 'welfare' or some such term. If we think people's liberty important, we should think it important enough not to violate it for the sake of promoting any such goal, even if it be called 'liberty' (1988: 33).

Property and the Market

Liberal political theory, then, fractures over the conception of liberty. But a more important division concerns the place of private property and the market order. For classical liberals liberty and private property are intimately related. From the eighteenth century right up to today, classical liberals have insisted that an economic system based on private property is uniquely consistent with individual liberty, allowing each to live her life --- including employing her labour and her capital --- as she sees fit. Indeed, classical liberals and libertarians have often asserted that in some way liberty and property are really the same thing; it has been argued, for example, that all rights, including liberty rights, are forms of property; others have maintained that property is itself a form of freedom (Gaus, 1994a; Steiner, 1994). A market order based on private property is thus seen an *embodiment* of freedom (Robbins, 1961: 104). Unless people are free to make contracts and to sell their labour, or unless they are free to save their incomes and then invest them as they see fit, or unless they are free to run enterprises when they have obtained the capital, they are not really free.

Classical liberals employ a second argument connecting liberty and private property. Rather than insisting that the freedom to obtain and employ private property is simply one aspect of people's liberty, this second argument insists that private property is the only effective means for the protection of liberty. Here the idea is that the dispersion of power that results from a free market economy based on private property protects the liberty of subjects against encroachments by the state. As F.A. Hayek argues, ‘There can be no freedom of press if the instruments of printing are under government control, no freedom of assembly if the needed rooms are so controlled, no freedom of movement if the means of transport are a government monopoly’ (1978: 149).

What has come to be known as ‘new’, ‘revisionist’, or ‘welfare state’ liberalism challenges this intimate connection between personal liberty and a private property based market order (Freeden, 1978; Gaus, 1983a; Macpherson, 1973: ch. 4). Three factors help explain the rise of this revisionist theory. First, the new liberalism arose in the late nineteenth and early twentieth centuries, a period in which the ability of a free market to sustain what Lord Beveridge (1944: 96) called a ‘prosperous equilibrium’ was being questioned (Gaus, 1983b). If a private property based market tended to be unstable, or could, as Keynes argued (1973 [1936]), get stuck in an equilibrium with high unemployment, new liberals came to doubt that it was an adequate foundation for a stable, free society. Here the second factor comes into play: just as the new liberals were losing faith in the market, their faith in government as a means of supervising economic life was increasing. This was partly due to the experiences of the First World War, in which government attempts at economic planning seemed to succeed (Dewey, 1929: 551-60); more importantly, this reevaluation of the state was spurred by the democratisation of western states, and the conviction that, for the first time, elected officials could truly be, in J.A. Hobson's phrase ‘representatives of the community’ (1922: 49). As D.G. Ritchie observed:

> be it observed that arguments used against ‘government’ action, where the government is entirely or mainly in the hands of a ruling class or caste, exercising wisely or unwisely a paternal or grandmotherly authority --- such arguments lose their force just in proportion as the government becomes more and more genuinely the government of the people by the people themselves (1896: 64).

The third factor underlying the development of the new liberalism was probably the most fundamental: a growing conviction that, so far from being ‘the guardian of every other right’ (Ely, 1992: 26), property rights generated an unjust inequality of power that led to a less-than-equal liberty (typically, ‘positive liberty’) for the working class. This theme is central to contemporary American liberalism, which combines strong endorsement of civil and personal liberties with, at best, an indifference, and often enough an antipathy, to private ownership. Once again, the seeds of this newer liberalism can be found in Mill's *On Liberty*. Although Mill insisted that the ‘so-called doctrine of Free Trade’ rested on ‘equally solid’ grounds as did the ‘principle of individual liberty’ (1991 [1859]: 105), he nevertheless insisted that the justifications of personal and economic liberty were entirely distinct. And in his *Principles of Political Economy* Mill consistently emphasises that it is an open question whether personal liberty can flourish without private property (1976 [1871]: 210), a position that Rawls was to reaffirm a century later (1971: 258).

Liberalism as a Philosophy

Although liberalism is, first and foremost, a political philosophy, ‘liberal’ has come to be employed to describe a group of comprehensive philosophies (Rawls, 1993), including a theories of ethics, value, the person and knowledge.

Liberal Ethics

Following Wilhelm von Humboldt (1993 [1854]), Mill's *On Liberty* based the case for the primacy of freedom on the goodness of developing individuality and the cultivating capacities:

> Individuality is the same thing with development, and...it is only the cultivation of individuality which produces, or can produce, well-developed human beings...what more can be said of any condition of human affairs, than that it brings human beings themselves nearer to the best thing they can be? or what worse can be said of any obstruction to good, than that it prevents this? (Mill, 1991 [1859]: 71)

This is not just a theory about politics: it is a substantive, perfectionist, moral theory about the good. And, on this view, the right thing to do is to promote development, and only a regime securing each individual extensive liberty can accomplish this. This moral ideal of human perfection and development dominated liberal thinking in the latter part of the nineteenth, and for most of the twentieth, century: not only Mill, but T.H. Green, L.T. Hobhouse, Bernard Bosanquet, John Dewey and even John Rawls show allegiance to variants of this perfectionist ethic and the claim that it provides the foundation for a regime of liberal rights. (Gaus, 1983a). And it is fundamental to the proponents of liberal autonomy discussed above as well as ‘liberal virtue’ theorists such as William Galston (1980). That the good life is necessarily a freely chosen one in which a person develops his unique capacities as part of a plan of life is probably the dominant liberal ethic of the past century.

This may seem a surprising claim given that, at least since the publication of Rawls's *Theory of Justice*, it

has generally been thought that the main moral dispute among liberals stems from the divide between utilitarians and rights theorists. This is, of course, a real divide, and in the last twenty years it has indeed come to dominate liberal debate. But interestingly, sometimes even those on opposite sides of this supposedly fundamental split advocate some version of liberal perfectionism. Thus the utilitarian-inspired J.S. Mill formulated the canonical version of liberal perfectionism while the apparently anti-utilitarian Rawls insists in his *Theory of Justice* that ‘human beings enjoy the exercise of their realized capacities (their innate and trained abilities), and this enjoyment increases the more the capacity is realized, or the greater its complexity’ (1971: 426; Gaus, 1981).

To say that liberal perfectionism has come to be a distinctly liberal ethic is not to merely assert that it is an ethic employed to defend liberal political positions. It is to make a stronger claim that liberals have come to understand the nature of moral rightness as founded on the pursuit of individuality and value of human development. In this light, it is less clear that utilitarianism constitutes a liberal ethic. To be sure, the notion of a ‘liberal utilitarianism’ is not an oxymoron; but neither is the term at all redundant. Interestingly, in his attempt to defend an explicitly *Liberal Utilitarianism*, Jonathan Riley advocates a social welfare function that restricts the domain of preferences to the ‘morally admissible’ or ‘ideal’, and these turn out to be those that reflect the sort of character ideal presented by Mill (1988: 83-92). Thus Riley liberalises utilitarianism by building in Mill's perfectionism. Given sufficient assumptions about human motivation, preferences, lack of knowledge and so on, a utilitarian ethic can endorse a liberal politics, but the relation between the two is highly contingent.

The main challenge to Millian perfectionism as a distinctly liberal ethic comes not from utilitarianism but from moral contractualism, which can be divided into what might very roughly be labeled ‘Kantian’ and ‘Hobbesian’ versions. According to Kantian contractualism, ‘society, being composed of a plurality of persons, each with his own aims, interests, and conceptions of the good, is best arranged when it is governed by principles that do not themselves presuppose any particular conception of the good...’(Sandel, 1982: 1-7). On this view, respect for the person of others demands that we refrain from imposing our view of the good life on them. Only principles that can be justified to all respect the personhood of each. Thus the tendency of recent liberal theory (Rawls, 1971; Reiman, 1990) to transform the social contract from an account of the state to an overall justification of morality, or at least a social morality. Basic to such ‘Kantian contractualism’ is the idea that individuals are motivated not by the pursuit of gain, but by a commitment or desire to publicly justify the claims they make on others (Reiman, 1990; Gaus, 1990; Scanlon, 1982). A moral code that could be the object of agreement among rational individuals is thus a publicly justified morality.

In contrast, the Hobbesian version of contractualism supposes only that individuals are self-interested, and correctly perceive that each person's ability to effectively pursue her interests is enhanced by a framework of norms that structure social life and divide the fruits of social cooperation (Gauthier, 1986; Kavka, 1986). Morality, then, is common framework that advances the self-interest of each. The claim of Hobbesian contractualism to be a distinctly liberal conception of morality stems from the importance of individual freedom and property in such a common framework: only systems of norms that allow each person great freedom to pursue her interests as she sees fit could, it is argued, be the object of consensus among self-interest agents. The continuing problem for Hobbesian contractualism is the apparent

rationality of free-riding: if everyone (or enough) comply with the terms of the contract, and so social order is achieved, it would seem rational to defect, and act immorally when one can gain by doing so. This is essentially the argument of Hobbes's ‘Foole’, and from Hobbes (1948 [1651]: 94ff) to Gauthier (1986: 160ff), Hobbesians have tried to reply to it.

Liberal Theories of Value

Turning from rightness to goodness, we can identify three main candidates for a liberal theory of value. We have already encountered the first: Millian perfectionism. Insofar as perfectionism is a theory of right action --- that rightness consists of promoting what Mill called ‘utility in the largest sense’, i.e., human development (1991 [1859]: 15) --- it can be understood as an account of morality. Obviously, however, it is an account of rightness that presuppose a theory of value or the good: the ultimate human value is developed personalities or an autonomous life. Competing with this objectivist theory of value are two other liberal accounts: pluralism and subjectivism.

In his famous defence of negative liberty, Isaiah Berlin insisted that values or ends are plural, and no interpersonally justifiable ranking among these many ends is to be had. More than that, Berlin maintained that the pursuit of one end necessarily implies that other ends will not be achieved. In this sense ends collide or, in the more prosaic terms of economics, the pursuit of one end necessarily entails opportunity costs in relation to others which cannot be impersonally shown to be less worthy. So there is no interpersonally justifiable way to rank the ends, and there is no way to achieve them all. The upshot is that each person must devote herself to some ends at the cost of ignoring others. For the pluralist, then, autonomy, perfection or development are not necessarily ranked higher than hedonistic pleasures, environmental preservation or economic equality. All compete for our allegiance, but because they are incommensurable, no choice can be interpersonally justified as correct.

The pluralist is not a subjectivist: that values are many, competing and incommensurable does not imply that they are somehow dependent on subjective experiences. But the claim that what a person values rests on experiences that vary from person to person has long been a part of the liberal tradition. To Hobbes, what one values depends on what one desires (1948 [1651]: 48). Locke advances a ‘taste theory of value’ (Gaus, 1986):

> The Mind has a different relish, as well as the Palate; and you will as fruitlessly endeavour to delight all Man with Riches or Glory, (which yet some Men place their Happiness in,) as you would satisfy all men's Hunger with Cheese or Lobsters; which, though very agreeable and delicious fare to some, are to others extremely nauseous and offensive: And many People would with reason preferr [sic] the griping of an hungry Belly, to those Dishes, which are a Feast to others. Hence it was, I think, that the Philosophers of old did in vain enquire, whether the *Summun bonum* consisted in Riches, or bodily Delights, or Virtue, or Contemplation: And they might have as reasonably disputed, whether the best Relish were to be found in Apples, Plumbs or Nuts; and have divided themselves into Sects upon it. For...pleasant Tastes depend not on the things themselves, but their agreeableness to this or that particulare Palate, wherein there is great variety...(1975 [1706]: 269).

The perfectionist, the pluralist and the subjectivist concur on the crucial point: the nature of value is such that people will pursue different ways of living. To the perfectionist, this is because each person has unique capacities, the development of which confers value on her life; to the pluralist, it is because values are many and conflicting, and no one life can include them all, or make the interpersonally correct choice among them; and to the subjectivist, it is because our ideas about what is valuable stem from our desires or tastes, and these differ from one individual to another. All three views, then, defend the basic liberal idea that people rationally follow very different ways of living. But in themselves, such notions of the good do not constitute a full-fledged liberal ethic, for an additional argument is required linking liberal value with norms of equal liberty. To be sure, Berlin seems to believe this is a very quick argument: the inherent plurality of ends points to the *political* preeminence of liberty (Kocis: 1980). Guaranteeing each a measure of negative liberty is, Berlin argues, the most humane ideal, as it recognises that 'human goals are many,' and no one can make a choice that is right for all people (1969: 171). But the move from diversity to equal liberty and individual rights seems a complicated one; it is here that both subjectivists and pluralists often rely on versions of moral contractualism. Those who insist that liberalism is ultimately a nihilistic theory can be interpreted as arguing that this transition cannot be made successfully: liberals, on their view, are stuck with a subjectivistic or pluralistic theory of value, and no account of the right emerges from it.

Liberal Epistemology

On the face of it, it may seem odd to think of a distinctively liberal theory of knowledge, but liberalism has always been closely associated with the Enlightenment and its defence of reason. Once again, we witness a split between two liberal camps. The rationalistic camp is best represented by Voltaire and the *philosophes* in whom it takes the form not only of a defence of science but an attack on superstition, custom and, importantly, religion. Thus the secular and anti-religious character of much liberal thought. This sort of militant, confident, rationalism is, however, also associated with great confidence in the ability of humans to understand nature and control their social world. According to Hayek, the flaw at the heart of utilitarianism stems from embracing this rationalism:

> The trouble with the whole utilitarian approach is that, as a theory professing to account for a phenomenon which consists of a body of rules, it completely eliminates the factors which makes rules necessary, namely our ignorance. It has indeed always amazed me how serious and intelligent men, as the utilitarians undoubtedly were, could have failed to take seriously this crucial fact of our necessary ignorance of most of the particular facts, and could have proposed a theory which supposes knowledge of the particular effects of our individual actions when in fact the whole existence of the phenomenon they set out to explain, namely a system of rules of conduct, was due to the impossibility of such knowledge (1976: 20).

Karl Popper (1945) made a similar charge against Plato, Hegel and Marx: *viz.* they failed to appreciate the limits of knowledge. Hayek and Popper, then, represent the other strain of liberal epistemology: an insistence that reason is limited, and our basic position is one of ignorance. This cautious, fallibilistic,

liberalism is less apt to be militantly secular than tolerant of religion; it is more likely to stress the incremental and experimental nature of social policy than to advocate grand social reconstructions. And it is more likely to appreciate the market, as a device for coping with our constitutional ignorance, and less likely to be enamored with state planning. To a significant extent, the marked differences between, on the one hand, British and Austrian liberalism and, on the other, French liberalism, stem from these different views of the power of reason in human affairs.

The Metaphysics of Liberalism

In his *Liberalism and the Limits of Justice* Michael Sandel charged that ‘Kantian liberals’ in general, and John Rawls in particular, are committed to a conception of the person according to which the self is in some way prior to its ends or substantive attachments. What has become known as the ‘communitarian critique of liberalism’ has insisted that this is implausible --- people are ‘constituted’ by their ends or values, and they cannot abstract from these particular ends and social commitments to deliberate on matters of justice from a ‘disembodied’ perspective. Although it is dubious that liberals are really committed to all *that*, it is surely the case that, overwhelmingly, liberals do believe that individual persons are ontologically prior to social groups and relations and, so, persons and their identities are distinct, and that central to personhood is a capacity to choose among alternative ways of living.

A perennial issue in liberal theory is the extent to which this basic individualism can be combined with a recognition of the social nature of humans, and the importance of one's social environment in the formation of personality. Stanley Benn is among those who insist that the liberal commitment to persons as choosers is in no way inconsistent with appreciating the importance of our social inheritance. The liberal individual, he insists, does not:

> conjure his *nomos* out of thin air, adopting it by a kind of random fancy, kicking aside the *nomoi* of his culture, its traditions, as so much clutter. One's reasons for engaging in an activity as worthwhile, for accepting the principles and standards that regulate it as constraining one's own performances, must already be built into one's conception of the world, which one must have received initially from those about one, as conceptual resources made available by the cluster of subcultures that combine to make one what one is --- or rather that provide the materials for what one can become (1988: 220-21).

It has been plausibly argued that the French, as opposed to the British liberal tradition, has taken more seriously these social influences on individuals and their lives (Seidentop, 1979). More generally, Will Kymlicka (1989) has argued that liberalism can indeed makes sense of ‘cultural membership’ and the way individual identities are dependent upon it. Yet it is unclear just how far liberalism's basic individualism permits accommodation with communitarian conceptions of the self, in which one's identity is bound up with a group identity (Gaus, 1983). Although the liberal can certainly acknowledge that we are both individual and social creatures, it seems doubtful that liberals can see individualised personalities as simply social artefacts of a particular, Western, culture: some sort of inherent individuation of personalities seems, as John Chapman argues (1977), a basic element of the liberal conception of human nature. Thus the worry that T.H. Green's or Bernard Bosanquet neo-Hegelian theory of the person is at

odds with their liberal politics. According Bosanquet's Absolute Idealism, individual persons are less real, because less complete and coherent, than the social whole (Gaus, 1994b). Moreover, Bosanquet insisted that ‘it is very hard to establish a difference in principle between the unity of what we call one mind and that of all the “minds” which enter into a single social experience’ (1923: 166).

The Return of a Purely Political Liberalism?

Prominent liberals have recently shied away from the conception of liberalism as a comprehensive philosophy, and have sought to return to its roots: as a purely political doctrine. This important development, aptly enough described as ‘political liberalism’, insists that liberalism as a comprehensive philosophy --- as including an ethical theory, an epistemology or a metaphysics of the person and society --- is just one more controversial or ‘sectarian’ doctrine in a society already filled with such doctrines. To John Rawls (1993: 5ff), the preeminent proponent of this view, such a ‘sectarian liberalism’ is open to rational dispute, and thus is not in the requisite sense publicly justified. If it is to serve as the basis for public reasoning in our diverse western societies, liberalism must be restricted to a core set of political principles that are, or can be, the subject of consensus among all reasonable citizens. Rawls's notion of a purely political conception seems in fact more austere than the traditional liberal political theories discussed above, being largely restricted to constitutional principles upholding basic civil liberties and the democratic process.

There are good grounds for doubting that liberalism can really rid itself of controversial metaphysical (Hampton, 1989) or epistemological (Raz, 1990; Gaus, 1996) commitments. As indicated above, Rawls seems to rest his case on the requirements of public justification, yet he seeks a distinctly political, non-epistemological, conception of justification (1993:44). And this, of course, because epistemological theories are controversial. We thus seem driven to the idea that a citizen could ‘politically justify’ a claim in a way that violates her epistemic standards of what constitutes a good reason. It is not at all clear, though, whether one could see oneself as having a politically justified claim on another while recognising that the argument for that claim depends on what, from one's epistemic perspective, are bad reasons (Gaus, 1996: 131ff).

Liberalism is, first and foremost, a political theory, yet it seems dubious that it can be a *purely* political theory. While no liberal need embrace every element of the wider liberal philosophy --- not every liberal must advance a liberal notion of the morally right, a liberal conception of value, a liberal epistemology and a liberal metaphysics of the person --- it is hard to see how any liberal political theory can avoid *all* of these. To be sure, no necessary principles mandate how political philosophy links up to the rest of philosophy. But neither is it an entirely autonomous field; hence the ‘comprehensive’ nature of all liberal theories.

Public Justification

The idea of public justification is the key idea in contemporary liberal-democratic political theory. The idea is, roughly, that no regime is *legitimate* unless it is reasonable from every individual's point of view. (As will be seen, this formula conceals considerable ambiguity.) Although John Rawls is the foremost exponent of the idea of public justification, its importance is also marked in the work of Jürgen Habermas, David Gauthier, and others. There is considerable current interest in the question of how the ideal of public justification is to be properly articulated. Some theorists, such as Rawls, seem to read 'reasonable from every individual's point of view' more or less 'empirically', whereas others, most notably Jerry Gaus, claim that this crucial phrase must be given a normatively-loaded reading. On the first account, something like actual (or only mildly idealized) agreement is required for legitimacy, whereas, on the second account, 'reasonable' means 'supported by good reasons'. If the first account is accepted, there is some danger that regimes will be judged legitimate which are supported only or mainly by 'bad' reasons--i.e. which depend for their 'legitimacy' on mistaken beliefs or on morally inadmissible desires and preferences. If the second account is accepted, demonstrations of legitimacy may not be practically efficacious--i.e. they may need to be supplemented by forceful impositions of requirements which, while supported by 'good reasons', are not actually accepted by the individuals concerned. Much work in the area is concerned with the degree to which these competing demands--of 'practical efficacy' and 'morality'--can be balanced to yield some *public conception* of public justification. (For a good overview of work in this area, see D'Agostino and Gaus, 1998.)

Situating the Idea of Public Justification

It may seem innocuous to suggest that the measure of legitimacy of regimes is fundamentally tied to discursive justifiability. This view is nevertheless controversial and, indeed, may be unsupportable.

On the first point, methodological conservatives such as F.A. Hayek and Michael Oakeshott would certainly be sceptical about the idea that legitimacy could be established discursively.

According to Hayek, this kind of approach embodies the ‘synoptic delusion’, or, in other words, the idea that it is possible to survey adequately the full range of information that might be relevant to determinations of legitimacy, to manipulate this information as needed, and to arrive, via reasoning, at some conclusion one way or another. Furthermore, any such attempt would fail, as other approaches might not, to take adequate account of the ‘dispersed knowledge’ of a large community. On Hayek's account, issues of legitimacy are largely responsible to processes of social evolution--that is, to make an assessment of legitimacy, you need to consider facts about the course of development of the institutions.

According to Oakeshott, a fully discursive treatment of complex political issues associated with legitimacy will fail on account of its inability to take adequate notice of the ‘tacit knowledge’ of practitioners. There is, on this account, much more that is relevant to determining legitimacy than could be expressly articulated, and much more, hence, than could ever be made available as ‘input’ to a justificatory course of reasoning.

These are, if you like, methodologically *traditionalist* alternatives to the rational, discursive, and intellectualized approach of the advocates of public justification.

Another point of contrast is with those approaches to politics which think that it is mistaken--perhaps corrupt--to seek the kind of stasis (however temporary) that seems to be implied in the idea that some determinate regime might be publicly justifiable and hence legitimate. On this account, the point of politics is not to resolve existing differences--which seems, at least in some sense, to be the point of attempting public justification; it is, rather, to keep alive those differences which are (i) fertile of edifying forms of controversy, and (ii) expressive of the irresolvable plurality of views, frameworks, and ‘life-styles’ in any decently ‘free’ and moderately diverse community.

Jean-Francois Lyotard seems to be an advocate of this position, and resistance to reduction to consensus is also implied by Michel Foucault's views on ‘normalization’; he says, for instance, that "The search for a form of morality acceptable to everyone ... seems catastrophic". On this account, the main mechanism for facilitating the achievement of public justification would have to be coercive; whether actually or from some normatively-loaded perspective that corrects for ‘ideological distortion’, people's interests are irreconcilable and hence can be brought only by coercion into sufficient alignment to support a claim to public justification. The very demand for public justification is hence itself implicitly *authoritarian*.

A final point of contrast is with those approaches which see in Rawlsian, Habermasian, and other mechanisms of public justification some attempt to *substitute* allegedly but not actually politically-innocent notions of rationality for self-admittedly political negotiation of conflict. Benjamin Barber is representative of this school, which wants to seek legitimacy where it can be found, not in the theorist's discourse on justification, but, instead, in institutionally-embodied, public, ‘real-time’ explorations of disputed issues. ‘We, the People’ must do the work of legitimation ourselves, on this account; no theorist's claims to have discovered some ‘overlapping consensus’ implicit in our public political culture can save us from this work. As with Lyotard and others of his ilk, members of this school see the theorist

of public justification as a closet authoritarian.

Contrasting Conceptions of Public Justification

As mentioned earlier, the phrase ‘reasonable from the point of view of every individual’ conceals numerous ambiguities. At least three are of special importance in understanding the great variety of different schemes for articulating the concept of legitimacy as justifiability.
